## COMPUTATIONAL STUDIES OF SULFONYLUREAS MOLECULES

## BY

## VUKEYA THEMBANI SILAS,

## STUDENT NUMBER: 11628584

This thesis is submitted in fulfilment of the requirements for the degree of Master's in chemistry.

SUPERVISOR: PROF. LILIANA MAMMINO<br>Department of Chemistry, University of Venda, Thohoyandou, South Africa

CO-SUPERVISOR: Dr. CATERINA GHIO
Institute for Physico-Chemical Processes, Molecular Modelling Lab, Pisa, Italy

April 2021
(C) University of Venda

## Declaration

I, Thembani Silas Vukeya hereby declare that this thesis for the award of a Master's degree in Chemistry, submitted by me, has never previously been submitted for a higher degree or diploma at this or any other University. And that to the best of my knowledge and belief, the thesis contains no material previously published or written by another person except where due reference is made in the thesis itself.

Signature: .. fulern...........
Date: 20 July 2021

## Acknowledgements

I would like to acknowledge the following for the help and support they provided:

- Professor L. Mammino (supervisor)
- Dr. Caterina Ghio (Co-supervisor)
- Mrs. M.K. Vukeya (Mother)
- My family
- Ms. N. Tshilande
- Dr S.S. Mnyakeni Moleele (HOD of chemistry department)
- Mr. D.O. Sipoyo
- My friends
- Sasol-NRF foundation for funding.
- Centre for High Performance Computing (CHPC) for allowing me access to utilize their platform to perform calculations

## Abstract

Computational studies are very important for biologically active molecules and for the development of new drugs, because the biological activities depend on their molecular structures and properties. This work presents the results of a conformational study of selected sulfonylureas molecules in vacuo. Sulfonylureas are a class of synthetic organic compounds containing a thiourea group (sulfonyl and urea groups bonded together) attached to a benzene ring, a substituent $(\mathrm{R})$ on the thiourea, and another substituent ( $\mathrm{R}^{\prime}$ ) linked to the benzene ring by a two- or threecarbon atom chain attached to an oxygen atom which is directly attached to the benzene ring in para position with respect to the thiourea group. The interest in this class of compounds is that some compounds are used in the treatment of type 2 diabetes. Molecules with different R and $\mathrm{R}^{\prime}$ substituents have been considered. Full-optimization calculations were performed in vacuo using Density Functional Theory (DFT) and Hartree Fock (HF) methods. Attention was given to the identification of stable conformers of each of the molecules considered (obtainable by rotation of relevant bonds) and of the conformers' stabilizing factors. The molecular properties considered include the relative energies of the conformers, the parameters of the intramolecular hydrogen bonds (IHBs), the dipole moments, the HOMO-LUMO energy gaps, and the vibrational frequencies of relevant bonds (in particular, the $\mathrm{N}-\mathrm{H}$ bonds, because the $\mathrm{N}-\mathrm{H}$ groups may be IHB donors).

The results indicate that the number and type of IHBs are the major stabilizing factors. A maximum of three simultaneous IHBs are possible in the thiourea group. This includes the presence of bifurcated IHBs (bifurcation on the hydrogen atom of the donor), which are present in most of the stable conformers. The vibrational frequencies of the $\mathrm{N}-\mathrm{H}$ bonds show changes occurring when these bonds form IHBs. The changes showed a rare phenomenon, that is, a blue shift (frequency increase) for certain IHBs, and also a much more common phenomenon (red shift. i.e., frequency decrease) for other IHBs. The geometry of the thiourea moiety, the nature of R and $\mathrm{R}^{\prime}$, the orientation and the length of the chain between the benzene ring and $\mathrm{R}^{\prime}$ also show some influence on the calculated molecular properties.

## Acronyms

ATP: Adenosine triphosphate
CHPC: Centre for High Performance Computing
DFT: Density Functional Theory
DME: Diabetic macular edema
GGA: Generalized gradient approximation
GTOs: Gaussian type orbitals
HF: Hartree-Fock

HOMO: Highest Occupied Molecular Orbital
IHB: Intramolecular Hydrogen Bond
KATP: ATP-dependent $\mathrm{K}^{+}$
LCAO: Linear Combination of Atomic Orbitals
LDA: Local Density Approximation

LUMO: Lowest Occupied Molecular Orbital
MP2: Møller-Plesset second order Perturbation Theory
MOs: Molecular Orbitals

NPDR: Non-proliferative diabetic retinopathy
PAD: Peripheral artery disease
PDR: Proliferative diabetic retinopathy
QSAR: Quantitative Structure-Activity Relationship
SCF: Self-Consistent Field
STOs: Slater Type Orbitals

PES: Potential energy surface
ZPE: Zero Point Energy

## Chapter 1

## Introduction

This chapter provides information about the objectives and justification of the study presented in this thesis, the computational methods utilised, and the organization of the material in this thesis.

### 1.1. Background information

This thesis presents the results of a computational study of selected sulfonylureas (figure 1.1). Sulfonylureas are synthetic organic compounds which are used in medicine as antidiabetic drugs. They are used for the treatment of type 2 diabetes [1]. They are commonly classified as first and second-generation sulfonylureas [2]. These compounds stimulate the production of insulin in the body. Some of them were found to have severe side effects; therefore, there is a need to search for new compounds which will work effectively with minimal or no side effects. The search for new antidiabetic drugs is very important because diabetes can lead to severe or life-threatening complications, including blindness and amputations.

Figure 1.1. General structure of the sulfonylureas molecules

Since the biological activities of molecules depend on their molecular properties, it is essential to find detailed information about the molecular properties of the compounds of interest. This information is relevant to understand the action of the given molecules, and in the development of new molecules (from drug design), and it is obtained through computational studies.

This work focuses on the computational study of 36 new selected sulfonylureas. These compounds are being considered for synthesis by organic chemistry researchers at the University of Venda.

Figures 1.2 shows the general structures of the two classes of sulfonylureas molecules investigated in this study. Six different substituents are considered for the R group (substituent attached to the sulfonylurea moiety) and three different substituents are considered for the $\mathrm{R}^{\prime}$ group (substituent attached to a carbon atom chain attached to an oxygen atom bonded to the benzene ring). Although the nitrogen atom $(\mathrm{N})$ is part of $\mathrm{R}^{\prime}$, it is indicated individually in the structures for clarity reasons.

Figure 1.2. General structures of the sulfonylureas molecules considered in this study. The two structures differ by the length of the chain between the oxygen atom attached to the benzene ring and the nitrogen atom belonging to $\mathrm{R}^{\prime}$.

### 1.2. Objectives of the study

The broad objective of the study is to obtain information about the selected sulfonylureas molecules. The specific objectives are the following:

- To identify the stable conformations of the selected sulfonylureas molecules, considering all the possible geometries obtainable by rotations about relevant single bonds.
- To identify the conformers' stabilizing factors.
- To determine the molecular properties of these molecules, such as conformational preferences, characteristics of intramolecular hydrogen bonds (IHBs), dipole moments, HOMO-LUMO energy difference, and IR vibrational frequencies of relevant bonds.
- To compare the molecular properties of different molecules in order to identify the effects of the various R and $\mathrm{R}^{\prime}$ substituents considered and, possibly, also to identify trends or patterns in these effects.

### 1.3. Justification of the study

Research on drugs for the treatment of diabetes is important because of the high number of people affected by the disease and the high number of deaths it causes. This work falls within a worldwide active search for improved sulfonylureas molecules for the treatment of diabetes, where 'improved' refers mostly to a decrease in the drawbacks of currently-used sulfonylureas, i.e., the occurrence of hypoglycemia episodes and the gradual decrease in the pancreas response to the drugs. An option for trying to improve on known drugs involves modifications of the molecular structure by using different substituents.

As already mentioned, the biological activity of molecules depends on their molecular properties; therefore, it is important to know as much as possible about these properties. In modern chemistry, there is an increasing tendency to interface experimental and computational research, as computational research can provide information that is useful for the interpretation of experimental findings. This work follows this trend and aims at providing new information which will add to the information currently available on sulfonylureas and may also contribute to the interpretation of the results of an experimental project conducted by other researchers in the same institution.

### 1.4. Computational methods and materials used

Electronic structure methods are selected for the molecular calculations in this study because they give more reliable information than non-quantum methods [3]. Both ab initio and Density Functional Theory (DFT) methods were used. This is because the use of different methods provides more complete information through the comparison of their results. For the ab initio calculations, the Hartree-Fock (HF) method was used with the $6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ basis set. The B3LYP functional with the $6-31+G(d, p)$ basis set was used for the DFT calculations. All the calculations were carried out with full geometry optimization (fully relaxed geometry), to identify stable conformations for each input geometry.

The Gaussian 16 [4] software was used for all the calculations, and GaussView [5] was used for visualization.

### 1.5. Organization of the materials

This thesis is organized in 6 chapters and an appendix, with the following roles:
Chapter 1 provides a quick background information about sulfonylureas, the justification and the objectives of the study and the tools and methods used for it.

Chapter 2 provides the theoretical background of the computational methods used in the study of molecules and information about molecular properties that can be calculated.

Chapter 3 provides information from literature on diabetes and on the sulfonylureas molecules.
Chapter 4 provides the results obtained in this study and their analysis and discussions.
Chapter 5 provides overall discussions and conclusions based on all the observation noted during the analysis of the results reported in chapter 4 , and considerations for future studies on the same class of molecules.

Chapter 6 presents most of the tables reporting numerical results, and most of the figures showing the obtained optimized molecular geometries, selected molecular orbitals, and comparison diagrams for relevant values. They are grouped in a separate chapter because they are very bulky, and they would disrupt the readability of the text if inserted in it.

Literature references for the whole thesis are listed after chapter 6.
Appendix A presents additional tables that may be useful for the analysis of some results.

## Chapter 2

## Theoretical background

### 2.1. Importance of the computational study of molecules

The computational study of molecules is important for determining molecular properties such as conformational preferences, geometry (bond lengths, bond angles and dihedral angles), dipole moments, molecular orbitals, and others. This study is important for molecules that are biologically active because biological activities depend on the molecular properties. It is particularly useful for the determination of molecular properties that are inaccessible experimentally, and it can help establish better understanding of the activities of biologically active molecules. It can also enable us to predict the molecular properties of molecules that have not yet been synthesized.

### 2.2. The description of molecules

A molecule is a stable assembly of nuclei and electrons. We can see it as being made of atoms. Each molecule is characterized by its composition (type and number of atoms), by its structure (arrangement of atoms in the molecule) and by properties that depends on the structure [6, 7]. The molecular structure can be determined experimentally using different spectroscopic techniques [811]. The chemical and physical properties of substances are different due to different molecular properties [12].

A molecule can take many geometries, with each geometry defined by three sets of parameters, i.e., bond length, bond angles and dihedral angles.

A bond length is defined as the average distance between the nuclei of two bonded atoms and it is expressed in Angstrom ( $1 \AA=10^{-10} \mathrm{~m}$ ) or pico-meter ( $1 \mathrm{pm}=10^{-12} \mathrm{~m}$ ) [9]. In a molecule, we consider a bond length for each pair of bonded atoms. For example, the bond lengths of the ethane molecule (figure 2.1) are the following distances: $\mathrm{C} 1-\mathrm{C} 2, \mathrm{C} 1-\mathrm{H} 3, \mathrm{C} 1-\mathrm{H} 4, \mathrm{C} 1-\mathrm{H} 5, \mathrm{C} 2-\mathrm{H} 6, \mathrm{C} 2-$ H7, C2-H8. The bond length is influenced by the size of the bonded atoms and by the multiplicity of the bonds. The bigger the atom size, the longer the bond length, and the smaller the atom size,
the shorter the bond length. When the number of bonds between two bonded atoms increases, the bond length between them decreases [13, 14]. For instances, the length of the $\mathrm{C}-\mathrm{C}$ single bond $(1.54 \AA)$ is greater than the length of the $\mathrm{C}=\mathrm{C}$ double bond $(1.34 \AA)$, which is greater than the length of the $\mathrm{C} \equiv \mathrm{C}$ triple bond ( $1.20 \AA$ ).

Figure 2.1. Structure of the ethane molecule.

A bond angle $(\theta)$ is the average angle between two consecutive bonds, that is, it is the angle identified by three subsequently bonded atoms [13, 15]. For example, the bond angles of the ethane molecule (figure 2.1) are the following: $\mathrm{C} 1-\mathrm{C} 2-\mathrm{H} 6, \mathrm{C} 1-\mathrm{C} 2-\mathrm{H} 7, \mathrm{C} 1-\mathrm{C} 2-\mathrm{H} 8, \mathrm{C} 2-\mathrm{C} 1-\mathrm{H} 3, \mathrm{C} 2-$ C1-H4, C2-C1-H5, H3-C1-H4, H3-C1-H5, H4-C1-H5, H6-C2-H7, H6-C2-H8, H7-C2-H8. Bond angles are influenced by the hybridization of atomic orbitals, the presence of lone pairs of electrons and the electronegativity of the atoms. When the s- character of hybrid orbitals increases, the bond angle between two consecutive bonds increases. For example, the angle between two sp ${ }^{3}$ hybrid orbitals is $109.5^{\circ}$, the angle between two $\mathrm{sp}^{2}$ hybrid orbitals is $120^{\circ}$ and the angle between two sp hybrid orbitals is $180^{\circ}$. The lone pairs of electrons tend to occupy more space than the pairs engaged in a bond; therefore, each lone pair tries to "squeeze" the bonded pairs closer to each other and the bond angle decreases. The higher the number of lone pairs, the smaller the angle between the bonds. An example is shown in figure 2.2: the HĈH bond angle in the methane molecule (with no lone pairs) is $109.5^{\circ}$; the HNH bond angle in the ammonia molecule (with one lone pair) is $107.0^{\circ}$; and the HÔH bond angle in the water molecule (with two lone pairs) is $104.5^{\circ}$ [15-18].

tetrahedral

ammonia

water

bent

Figure 2.2. Decrease in the bond angle as the number of lone pairs of electrons in the molecule increases. Methane has no lone pair; ammonia has one lone pair and water has two lone pairs [19].

A dihedral or torsion angle is defined for groups of four atoms subsequently bonded in a chain [13]. If we number the four atoms as atoms $1,2,3$ and 4 , the dihedral angle can be defined as the angle between the plane identified by the first three atoms (atoms 1, 2 and 3) and the plane identified by the last three atoms (atoms 2, 3 and 4); it can also be seen as the angle by which the 3-4 bond must be rotated so as to eclipse the 1-2 bond. In the case of the ethane molecule (figure 2.1), we can identify the following dihedral angles: $\mathrm{H} 3-\mathrm{C} 1-\mathrm{C} 2-\mathrm{H} 6, \mathrm{H} 3-\mathrm{C} 1-\mathrm{C} 2-\mathrm{H} 7, \mathrm{H} 3-\mathrm{C} 1-\mathrm{C} 2-$ H8, H4-C1-C2-H6, H4-C1-C2-H7, H4-C1-C2-H8, H5-C1-C2-H6, H5-C1-C2-H7, H5-C1-C2-H8.

A molecule can take several different geometries. It can change from one geometry to another by rotation around a single bond. Some of these geometries correspond to minima on the potential energy surface (PES, a multi-dimension diagram obtained by changing molecular parameters such as bond length, bond angles or dihedral angles by specific amounts [20, 21]). The geometries corresponding to the minima on the PES are called conformers [22]. A search for the conformers of a given molecule is referred to as conformational search.

Bond lengths, bond angles and dihedral angles are the internal coordinates of a molecule [3]. When
preparing inputs for calculations, we can describe the starting geometry of the molecule in terms of the internal coordinates ( $Z$ matrix), or we can give the cartesian coordinates ( $x, y, z$ ) of each atom. Each atom in a molecule has three coordinates and, therefore, it has 3 degrees of freedom. If there are N atoms in a molecule, the total number of degrees of freedom is 3 N . In this work, all the inputs were prepared using the cartesian coordinates of the atoms [23].
As already mentioned, the PES is a multi-dimension diagram. It shows how the energy changes when some of the parameters of the molecule are changed. It can be visualized only in two or three dimensions [3, 23]. A two-dimension PES shows how the energy changes when one parameter is changed. A three-dimension PES shows how the energy changes when two parameters are changed. The stationary points on the PES are the points where the first derivative of the energy with respect to the parameter that is being changed is zero [3]. They can be minimum, maximum or saddle points. In order to know whether a stationary point identified by an optimization procedure is a minimum, we consider the vibrational frequencies. If all the vibrational frequencies are real for that geometry, then that point is a minimum point. There can be more than one minimum in the PES. Figure 2.3 shows an example of a two-dimension PES, where there are several local minima. The minimum which correspond to the lowest energy is called global minimum. There can be also several maxima and saddle points.

Figure 2.3. Example of a two-dimension potential energy surface (PES) showing local minima, the global minimum and a maximum [24].

The PES can also be considered for chemical reactions [25]. The equilibrium geometries of the reactants and products correspond to minimum points and the transition states are represented by first order saddle points, as illustrated in figure 2.4.

Figure 2.4. Example of a three-dimensional PES also considering a chemical reaction [20]

### 2.3. Computational methods for the study of molecules

Molecules can be studied using different methods. These methods can be classified into electronic structure methods and molecular mechanics [26]. The electronic structure methods comprise $a b$ initio, semi-empirical and Density Functional Theory methods. This works uses electronic structure methods and, therefore, these are the methods discussed in the next sections. The electronic structure methods consider solving the Schrödinger equation.

### 2.3.1. The Schrödinger equations

In quantum mechanics, an atom or a molecule is described by the solutions of its Schrödinger equation [27-30]. The general form of the Schrödinger equation is the following:

$$
\begin{equation*}
\hat{H} \psi_{i}=E_{i} \psi_{i} \tag{1}
\end{equation*}
$$

where $\hat{\mathrm{H}}$ is the Hamiltonian operator, i.e., the energy operator $\psi_{\mathrm{i}}$ is the total wavefunction of the $\mathrm{i}^{\text {th }}$ state (eigenfunction) $\mathrm{E}_{\mathrm{i}}$ is the energy value corresponding to $\psi_{\mathrm{i}}$ (eigenvalue corresponding to $\psi_{\mathrm{i}}$ ).

The solution of the Schrödinger equation for a molecule are the molecular orbitals (MOs) of that molecule.

The Hamiltonian operator contains all the energy terms of the system, comprising both kinetic and potential energies. The kinetic energy terms are expressed in the form:

$$
\begin{equation*}
E_{\text {kinetic }}=-\frac{\hbar^{2}}{2 m}\left(\frac{\partial^{2}}{\partial \mathrm{x}^{2}}+\frac{\partial^{2}}{\partial \mathrm{y}^{2}}+\frac{\partial^{2}}{\partial \mathrm{z}^{2}}\right) \tag{2}
\end{equation*}
$$

where $m$ is the mass of the particle, $\hbar$ is the Planck's constant divided by $2 \pi\left(\hbar=\frac{h}{2 \pi}\right)$ and the terms in parentheses are the Laplacian operator $\nabla^{2}$

$$
\begin{equation*}
\nabla^{2}=\frac{\partial^{2}}{\partial \mathrm{x}^{2}}+\frac{\partial^{2}}{\partial \mathrm{y}^{2}}+\frac{\partial^{2}}{\partial \mathrm{z}^{2}} \tag{3}
\end{equation*}
$$

The potential energy terms are the terms expressing the electrostatic attractions or repulsion between the particles.

The complete Hamiltonian for the study of a molecule can be expressed by [29]:

$$
\begin{equation*}
\hat{\mathrm{H}}=-\sum_{i}^{N} \frac{\hbar^{2}}{2 m_{\mathrm{e}}} \nabla_{\mathrm{i}}^{2}-\sum_{k}^{M} \frac{\hbar^{2}}{2 m_{\mathrm{k}}} \nabla_{\mathrm{k}}^{2}-\sum_{i}^{N} \cdot \sum_{k}^{M} \frac{e^{2} Z_{\mathrm{k}}}{r_{\mathrm{ik}}}+\sum_{i<j}^{M} \frac{e^{2}}{r_{\mathrm{ij}}}+\sum_{k<p}^{M} \frac{e^{2} Z_{\mathrm{k}} Z_{p}}{r_{k p}} \tag{4}
\end{equation*}
$$

where: i and j are electrons
k and p are nuclei
$\hbar$ is the Planck's constant divided by $2 \pi$
$m_{e}$ is the mass of the electron
$m_{k}$ is the mass of nucleus $k$
$e$ is the charge of the electron
N is the number of electrons in the molecule
M is the number of nuclei in the molecule

$$
\begin{aligned}
& Z_{k} \text { is the atomic number of nucleus } k \\
& Z_{l} \text { is the atomic number of nucleus } l \\
& r_{j k} \text { is the distance between electron } i \text { and nucleus } k \\
& r_{i j} \text { is the distance between electron } i \text { and electron } j \\
& r_{k l} \text { is the distance between nucleus } k \text { and nucleus } l \\
& \nabla_{\mathrm{i}}^{2} \text { is the Laplacian operator of electron } \mathrm{i} \\
& \nabla_{\mathrm{k}}^{2} \text { is the Laplacian operator of electron } \mathrm{k}
\end{aligned}
$$

The first term in the Hamiltonian (equation 4) represents the kinetic energy of the N electrons in the molecule and the second term represents the kinetic energy of the M nuclei. The third term is the potential energy of the electrostatic attraction between the nuclei and the electrons, the fourth term is the potential energy of the electron-electron repulsion and the last term is the potential energy of the nuclei-nuclei repulsion [31].

The Schrödinger equation grows more complex as the number of electrons in the system increases. It can be solved exactly (analytically) only for one-electron systems. In all the other cases, we need to use approximations.

### 2.3.2. The Born-Oppenheimer approximation

All the terms in the Hamiltonian are necessary for a full description of a molecule. On the other hand, it is not possible to solve the equation exactly. Approximations of different types are introduced, and the most common approximation is the Born-Oppenheimer approximation. In a molecule, the nuclei move much more slowly than the electrons because they have much greater mass. The Born-Oppenheimer approximation considers the nuclei as stationary and the Schrödinger equation is written only for the motion and the energy terms pertaining to the electrons [32-34]. Therefore, within this approximation, the Hamiltonian is the electronic Hamiltonian and is expressed by:

$$
\begin{equation*}
\hat{\mathrm{H}}_{\mathrm{el}}=-\sum_{i}^{N} \frac{\hbar^{2}}{2 m_{\mathrm{e}}} \nabla_{\mathrm{i}}^{2}-\sum_{i}^{N} \cdot \sum_{k}^{M} \frac{e^{2} Z_{\mathrm{k}}}{r_{\mathrm{ik}}}+\sum_{i<j}^{N} \frac{e^{2}}{r_{\mathrm{ij}}} \tag{5}
\end{equation*}
$$

When we study a molecule, we consider a certain set of nuclear distances and calculate the energy. Afterwards, we change the nuclear distances and other parameters and calculate the energy again.

The procedure is repeated until we find the geometry that give the lowest energy.

### 2.3.3. $\boldsymbol{A} b$ initio methods

Ab initio means "from the beginning" [35]. It involves solving the Schrödinger equation analytically, which means that all the integrals are solved with mathematical methods, whether they are solved exactly, or whether they are solved using mathematical approximations, but without including any experimental values [36, 37]. The most common ab initio methods are Hartree-Fork (HF), Møller-Plesset Perturbation Theory (MP2) and a variety of configurations interaction (CI), which are usually post Hartree-Fock methods. In this work, MP2 and CI are not used, so they will not be discussed in detail.

### 2.3.3.1. The Hartree-Fock method

The HF method is a recursion procedure, i.e. a series of steps are repeated, with each of them giving better results than the previous step. The easiest way to explain a recursion procedure is by considering all the steps of the Hartree procedure for the study of a multi-electron atom with atomic number Z , i.e. an atom with Z electrons [38-42]:

- Step 1: We consider the Z electrons to be moving independently; we can then consider a guess potential as a sum of a set of Z identical net potentials, with each set depending on the radial coordinate (r) of only one electron.
- Step 2: We use the net potential to express the Hamiltonian operator and the Schrödinger equation for the atom.
- Step 3: By applying the separation of variables technique to solve the Schrödinger equation, we obtain Z identical differential equations, each of them depending on the coordinates of one electron.
- Step 4: Each of the obtained differential equation is solved, and we obtain the wavefunctions and the corresponding energy values.
- Step 5: We consider the filling of the newly found quantum states and write the electronic configuration of the ground state of the atom.
- Step 6: The charge distribution of each electron is evaluated as a product of its charge and the probability density function.
- Step 7: The charge distribution of Z-1 electrons is then added to the nuclear charge in order
to find the total charge distribution of the atom as seen by a typical electron.
- Step 8: On the basis of the charge distribution, we can calculate the produced electric field by using Gauss's law of electrostatics.
- Step 9: The integral of the electric field is evaluated, and it is a more accurate estimate of the net potential experienced by a typical electron.
- Step 10: The obtained net potential is compared with the value of the potential used at the beginning of the loop. If the difference is greater than a preselected value, the new potential is used to write the Hamiltonian and the Schrödinger equation (as in step 2), and the series of steps ( 3 to 10) is repeated. If the difference is less than the preselected value, then we say that the procedure has converged. The net potential is the self-consistent solution and the obtained wavefunctions describe the ground state of the atoms. The self-consistency is related to the fact that we obtain the results by using several cycles of steps.

The values found in this loop are the solutions for that atom (self-consistent field results)

Figure 2.5. A flow chart showing the steps involved in the HF method [43]

### 2.3.3.2. Linear combinations of atomic orbitals (LCAO) and the variational principle

The solutions of the Schrödinger equations for a molecule are the molecular orbitals. Since we cannot solve the Schrödinger equation exactly, we have to use approximation methods. One of the approximations concerns the way of expressing the molecular orbitals. It is convenient to express them in terms of the atomic orbitals of the atoms of which a given molecule consists [44-46]. Therefore, this approximation expresses the molecular orbitals as a linear combination of atomic orbitals (LCAO).

$$
\begin{equation*}
\psi=\sum_{\mathrm{i}} c_{\mathrm{i}} \chi_{\mathrm{i}} \tag{6}
\end{equation*}
$$

where, $\psi$ is a molecular orbital (MO)
$\chi_{\mathrm{i}}$ are the atomic orbitals used for the expansion of $\psi$ $c_{\mathrm{i}}$ are the atomic orbital coefficients.

We consider atomic orbitals for each atom in the molecule. All the $\chi_{i}$ used for the MOs of a molecule constitute the basis set of the expansion. The atomic orbitals coefficients $c_{i}$ are related to the contribution of a given orbital $\left(\chi_{i}\right)$ to the whole molecular orbital [47].

As already mentioned, whenever we solve a Schrödinger equation, we are looking for a minimum in the potential energy surface of the system considered (section 2.2). This means that we want to minimize the energy. In order to do this, we write the expression of the energy, we express the wavefunction in terms of equation 6 , and we consider the conditions for the energy to be minimum. This will enable us to find the value of the coefficients $c_{\mathrm{i}}$ in the expansion. The variational principle ensures that, by using this method, we do not find energy values that are lower than the real value [48].

The variational principle states that, if a trial wavefunction is used to calculate the energy, the obtained values will not be less than the true energy value. The function expressed in terms of equation 6 is the trial function in the LCAO procedure. The energy value is expressed as an expectation value:

$$
\begin{equation*}
E=\frac{\int \psi^{*} \hat{\mathrm{H}} \psi d \tau}{\int \psi^{*} \psi d \tau} \tag{7}
\end{equation*}
$$

If we consider real wavefunctions, we can then write:

$$
\begin{equation*}
E=\frac{\int \psi \hat{\mathrm{H}} \psi d \tau}{\int \psi^{2} d \tau} \tag{8}
\end{equation*}
$$

By substituting equation 6 into equation 7, the expectation value of the energy can be written as

$$
\begin{equation*}
E=\frac{\int\left(\sum_{\mathrm{i}} c_{\mathrm{i}} \chi_{\mathrm{i}}\right) \hat{\mathrm{H}}\left(\sum_{\mathrm{i}} c_{\mathrm{i}} \chi_{\mathrm{i}}\right) d \tau}{\int\left(\sum_{\mathrm{i}} c_{\mathrm{i}} \chi_{\mathrm{i}}\right)^{2} d \tau} \tag{9}
\end{equation*}
$$

In order to find the minimum energy, we have to take the first derivative of the expectation value with respect to each of the coefficients and set it to be equal to zero. In this way we obtain a set of equations having the mathematical form

$$
\begin{equation*}
\left(\frac{\partial E}{\partial c_{i}}\right)_{\mathrm{j}, \mathrm{j} \neq \mathrm{i}}=0 \tag{10}
\end{equation*}
$$

By replacing the expression of E from equation 9 in each of these equations, we obtain a set of equations where the unknown quantities are the coefficients $c_{\mathrm{i}}$ and the energy E . These equations that are called the secular equations. In order to solve them, we have to set the determinant of the coefficients of the unknown quantities equal to zero. The determinant is called the secular determinant [41, 42].

For illustration purpose, we can consider the case of two atoms, i.e. the case of a heteronuclear diatomic molecule consisting of two atoms, A and B . The wavefunction can be expressed as

$$
\begin{equation*}
\psi=c_{A} \psi_{A}+c_{B} \psi_{B} \tag{11}
\end{equation*}
$$

where $\psi_{A}$ and $\psi_{B}$ are the atomic orbitals contributing to the molecular orbital $\psi$, and $c_{A}$ and $c_{B}$ are
the coefficients to be determined.

By substituting equation 11 into equation 7, the expectation value becomes

$$
\begin{equation*}
E=\frac{\int\left(c_{A} \psi_{A}+c_{B} \psi_{B}\right) \hat{\mathrm{H}}\left(c_{A} \psi_{A}+c_{B} \psi_{B}\right) d \tau}{\int\left(c_{A} \psi_{A}+c_{B} \psi_{B}\right)^{2} d \tau} \tag{12}
\end{equation*}
$$

By expanding the expressions of the numerator and the denominator, we obtain certain integrals that are given specific names; these are the Coulomb integrals $(\alpha)$, the resonance integrals $(\beta)$ and the overlap integrals (S). They are defined as follows:

$$
\begin{align*}
& \alpha_{A}=\int \psi_{A} \hat{\mathrm{H}} \psi_{A} d \tau  \tag{13a}\\
& \alpha_{B}=\int \psi_{B} \hat{\mathrm{H}} \psi_{B} d \tau  \tag{13b}\\
& \beta=\int \psi_{A} \hat{\mathrm{H}} \psi_{B} d \tau  \tag{14}\\
& S_{A B}=\int \psi_{A}^{*} \psi_{B} d \tau \tag{15}
\end{align*}
$$

In order to solve the secular equations, we set the secular determinant equal to zero.

$$
\left|\begin{array}{ll}
\alpha_{A}-E & \beta-E S  \tag{16}\\
\beta-E S & \alpha_{B}-E
\end{array}\right|=0
$$

The determinant is expanded to a quadratic equation in $E$ and then solved. The roots obtained are the energies of the bonding and antibonding molecular orbitals formed from the basis sets considered. The introduction of those energy values into the secular equation yields the coefficients $C_{A}$ and $C_{B}$.

### 2.3.3.3. Complying with the antisymmetry requirements

For any multi-electron system, we have to consider the spin of the electrons. Therefore, the total wavefunction is a function of the space coordinates of the electrons and the total spin angular momentum [30, 38, 47-51].

$$
\begin{equation*}
\text { total wavefunction }=(\text { space wavefunction }) \times(\text { spin wavefunction }) \tag{17}
\end{equation*}
$$

In the case of molecules, these wavefunctions are called spinorbitals. The spinorbitals can be expressed in the form:

$$
\begin{equation*}
\chi\left(\vec{x}_{\mathrm{i}}\right)=\phi(\vec{r}) \sigma \tag{18}
\end{equation*}
$$

where $\phi(\vec{r})$ is a function depending on the space coordinates of the electron, $\vec{r}$ is a vector of the space coordinates of the electron and $\sigma$ is a spin component taking into account the spins of all the electrons. For N electrons, the wavefunctions are written as the product of the spinorbitals, and this is called the Hartree product.

Since the electrons are fermions, we have to consider the Pauli's exclusion principle. The principle can be expressed through any of the following conditions [38]:

- Weaker condition: in a multi-electron atom, there can never be more than one electron in a given quantum state.
- Stronger condition: a system with several electrons must be described by an antisymmetric total wavefunction.

A function is antisymmetric if it changes sign when the two particles are exchanged (this is equivalent to changing the labelling of the two electrons). In the case of two particles, we can have only one exchange of the particles, so, there is only one permutation and the function can change sign. The total wavefunction can be antisymmetric with one of the two following options:
$($ antisymmetric total wavefunction $)=($ symmetric space wavefunction $) \times($ antisymmetric spin wavefunction)
$($ antisymmetric total wavefunction $)=($ antisymmetric space wavefunction $) \times($ symmetric
spin wavefunction)

In the case of many electrons, there are many options for permuting two of them. Therefore, it is possible to have many permutations of two particles simultaneously. Each permutation implies a change in the sign of the wavefunction. Whether the overall sign of the wavefunction changes depends on the number of permutations considered. If the number of permutations is odd, the overall result is the change of sign $[49,52,53]$. If the number of permutations is even, there will be no change in sign in the overall result. In order to consider the overall outcome, the wavefunction is written in the form of a Slater determinant [52]:

$$
\Phi_{\mathrm{SD}}=\frac{1}{\sqrt{\mathrm{~N}!}}\left[\begin{array}{cccc}
\chi_{1}\left(\vec{x}_{1}\right) & \chi_{2}\left(\vec{x}_{1}\right) & \cdots & \chi_{N}\left(\vec{x}_{1}\right)  \tag{20}\\
\chi_{1}\left(\vec{x}_{2}\right) & \chi_{2}\left(\vec{x}_{2}\right) & \cdots & \chi_{N}\left(\vec{x}_{2}\right) \\
\vdots & \vdots & \ddots & \vdots \\
\chi_{1}\left(\vec{x}_{N}\right) & \chi_{2}\left(\vec{x}_{N}\right) & \cdots & \chi_{N}\left(\vec{x}_{N}\right)
\end{array}\right]
$$

where: the electrons are numbered $1,2, . ., \mathrm{N}$
$\Phi$ is the wavefunction
$\frac{1}{\sqrt{\mathrm{~N}!}}$ is the normalisation coefficient.
N is the total number of electrons
$\vec{x}_{i}$ are coordinate vectors
$\chi_{i}\left(\vec{x}_{j}\right)$ is the function of the electron i considered for the coordinate vector $\vec{x}_{j}$

The Hartree-Fock approximation uses a single Slater determinant for the description of electronic wavefunctions [54]. The Hartree-Fock energy can be written in terms of integrals. Considering two-electron operators, it is expressed as

$$
\begin{equation*}
E_{H F}=\left\langle\Phi_{\mathrm{SD}}\right| \hat{\mathrm{H}}\left|\Phi_{\mathrm{SD}}\right\rangle=\sum_{i}^{N}\langle i| \hat{h}|i\rangle+\frac{1}{2} \sum_{i}^{N} \sum_{j}^{N}\langle i i \mid j j\rangle+\langle i i \mid j j\rangle \tag{21}
\end{equation*}
$$

where $\langle i i \mid j j\rangle=\iint\left|\chi_{i}\left(\vec{x}_{1}\right)\right|^{2} \frac{1}{r_{12}}\left|\chi_{i}\left(\vec{x}_{2}\right)\right|^{2} d \vec{x}_{1} d \vec{x}_{2}$

$$
\begin{equation*}
\left\langle\Phi_{\mathrm{SD}}\right| \hat{\mathrm{H}}\left|\Phi_{\mathrm{SD}}\right\rangle=\int \Phi_{\mathrm{SD}} \hat{\mathrm{H}} \Phi_{\mathrm{SD}} d \tau \text { (assuming that the wavefunction is normalized) } \tag{22}
\end{equation*}
$$

The resulting two-electron integral is given by

$$
\begin{equation*}
\langle i i \mid j j\rangle=\iint \chi_{i}\left(\vec{x}_{1}\right) \chi_{j}^{*}\left(\vec{x}_{1}\right) \frac{1}{r_{12}} \chi_{j}\left(\vec{x}_{2}\right) \chi_{i}^{*}\left(\vec{x}_{2}\right) d \vec{x}_{1} d \vec{x}_{2} \tag{23}
\end{equation*}
$$

### 2.3.3.4. Electron correlation

In the HF method, the motion of each electron is viewed as not being influenced by the motion of the other individual electrons (the repulsion with the other electrons is averaged). In reality, electrons influence each other's motions. It is said that their motions are correlated [55]. The energy associated with this correlation is called correlation energy and it is viewed as the difference between the exact energy and the energy of the best possible HF calculation (energy of the HF limit).

### 2.3.3.5. Basis sets

A basis set is defined as a set of functions used to create molecular orbitals [47, 56]. The MOs are expanded as a linear combination of atomic orbitals with coefficients to be determined (eqn. (6); section 2.3.3.2). Choosing the right basis set is very critical for the quality of the results.

Atomic orbitals contributing to the formation of molecular orbitals include:

- Core orbitals, which are the orbitals of the inner, closed shells of the atom
- Valence orbitals, which are the orbitals of the valence shell of the atom
- Virtual orbitals, which are orbitals that are unoccupied in the ground state of the atom [57, 58].

Basis sets may include different numbers and types of orbitals (sections 2.3.3.5.2-2.3.3.5.4).

### 2.3.3.5.1. Types of functions involved in basis sets

The most straightforward way would be to use atomic orbitals directly, for example, the solution of the hydrogen atom. The difficulty was that they have to be supplemented for completeness. The Slater type orbitals (STOs) were used in the early days in quantum chemistry as basis functions due to their similarities with the wavefunctions of the hydrogen atom [54, 59, 60].

$$
\begin{equation*}
R(r)=N r^{n-1} e^{-\xi r} \tag{24}
\end{equation*}
$$

where $R$ is the radium of the atomic nucleic distance
N is a normalisation constant
n is a natural number representing a principal quantum number, $\mathrm{n}=1,2 \ldots$,
$\xi$ is a constant related to the effective charge of the nucleus
$r$ is the distance of the electron from the atomic nucleus

An advantage of the STOs was their direct physical interpretation [60-65]. However, STOs had a severe shortcoming, because the integrals required during the SCF procedure must be calculated numerically, which reduces the computational speed.

Gaussian type orbitals (GTO) were then introduced to approximate the STOs, by expressing them as linear combinations of gaussian orbitals. GTOs are referred to as gaussian primitives, which are usually obtained from quantum calculations of atoms [62, 66].

$$
\begin{equation*}
G_{n l m}(r, \theta, \varphi)=N_{n} r^{n-1} e^{-\alpha r^{2}} Y_{l}^{m}(\theta, \varphi) \tag{25}
\end{equation*}
$$

where: $n, m, l$ are the quantum numbers
$\theta, \varphi$ are the angular coordinates.

The exponents are varied until the lowest possible energy is obtained.

### 2.3.3.5.2. Minimal basis set

A minimal basis set is a basis set containing only the functions necessary to accommodate the electrons in the atom [47, 67]. Usually, a single basis function is used in the Hartree-Fock calculations of a free atom (for instance, 1s for the H atom). The most common minimal basis set is STO-nG, where n is an integer representing the number of GTOs used to approximate the STOs for both the valence and core orbitals. Since this basis set is not flexible, the use of additional functions is considered a better option to represent orbitals more accurately. For example, the 1 s , $2 \mathrm{~s}, 2 \mathrm{p}_{\mathrm{x}}, 2 \mathrm{p}_{\mathrm{y}}, 2 \mathrm{p}_{\mathrm{z}}$ functions will be used for a lithium atom.

### 2.3.3.5.3. Polarized basis set

Polarisation refers to the distortion in the shape of an atomic orbital when the molecule is formed, due to the attraction of the electrons by the other nuclei [47, 69]. To take this phenomenon into account, basis functions with higher angular momentum quantum number ( $d$ and $f$ type) are added so as to increase the flexibility of the resulting MOs. The additional flexibility provided by the polarization functions enables the MO to be asymmetric about the nucleus [69]. This allows for more accurate description of the bonding between atoms by removing the spherical symmetry around an atom. The polarisation functions are essential for a better description of chemical bonding and should be considered in all calculations where electron correlation is important. An asterix $\left(^{*}\right)$ is used to inform that a polarization function has been added to the heavier atom, and a double asterix $\left({ }^{* *}\right)$ is used to inform that the polarisation function is added to both the heavier and the lighter atoms. For example, 6-31G* (or 6-31G(d)) informs that the polarization function has been added to the heavier atoms, that is, d orbitals have been added for carbon and other atoms of the second period. 6-31G** (or 6-31G(d, p)) informs that the polarisation function has been added to both the heavier and the lighter atoms, that is, d orbitals have been added for atoms of the second period and the $p$ orbital have been added for hydrogen atoms.

### 2.3.3.5.4. Diffuse basis set

Diffuse basis sets are basis sets which contain diffuse functions. The diffuse functions are usually of the $s$ and $p$ type orbitals [70]. They are considered important for the description of anions and weak bonds correctly and are relevant in the calculation of molecular properties such as dipole moments. The presence of diffuse function is denoted by + . For example, the basis set $6-31+G^{* *}$ is a basis set in which polarisation functions have been added for both the light and heavy atoms and the diffuse functions have been added for heavy atoms. The basis set $6-31++\mathrm{G}^{* *}$ is a basis set in which polarisation functions have been added for both the light and heavy atoms and the diffuse functions have also been added for both the light and heavy atoms.

### 2.3.3.4. Post-Hartree-Fock methods

The post HF methods are methods that are developed as an improvement on the HF results. They include electron correlation as a more accurate way to consider the electron-electron repulsions than in the HF method $[65,70]$. Some of the methods are MP2 and $\operatorname{CCSD}(T)$, (coupled cluster
methods); they will not be discussed here because they have not been used in this work.

### 2.3.4. Density functional theory (DFT)

### 2.3.4.1. General features of DFT

The DFT method is one of the most commonly used computational method for predicting the properties of chemical systems [71, 72]. Since the energy of the molecule can be determined in its ground state $\left(\mathrm{E}_{0}\right)$ from the electron density $(\rho)$, DFT attempts to calculate the ground state molecular properties from the ground state electron density without using the wavefunction of the system [73, 74]. DFT considers the energy as a function of the electron density

$$
\begin{equation*}
\mathrm{E}=\mathrm{E}(\rho) \tag{26a}
\end{equation*}
$$

Since $\rho$ is a function of the position $[\rho=\rho(\mathrm{r})]$, the energy is a function of a function (functional), as expressed by the equation:

$$
\begin{equation*}
\mathrm{E}=\mathrm{E}[\rho(\vec{r})] \tag{26b}
\end{equation*}
$$

DFT takes into account electron correlation (section 2.3.3.4.) and it has the advantage that it requires less computing power in comparison to most of the post HF-methods. The DFT theory is also based on the idea that an external potential $\left(\mathrm{V}_{\mathrm{ext}}\right)$ originating from a position of the nuclei in a molecule is a function of the electron density [75-79]. Due to this, two different external potentials can only yield different ground state electron densities.
The Hamiltonian ( $\hat{\mathrm{H}}$ ), is a functional of the electron density given by [29]:

$$
\begin{equation*}
\hat{\mathrm{H}}=\widehat{T}+\widehat{V}_{\mathrm{ee}}+\widehat{V}_{\mathrm{ext}} \tag{27}
\end{equation*}
$$

where: $\hat{T}$ is the kinetic energy of the non-interacting electrons
$\widehat{V}_{\text {ee }}$ is the external potential related to the classical electron-electron repulsion
$\widehat{V}_{\text {ext }}$ is the external potential related to the nuclear-electron interaction

The energy of a molecule in its ground state ( $\mathrm{E}_{0}$ ), generated from the ground state electron density, can be expressed by the equation:

$$
\begin{equation*}
\mathrm{E}_{0}=\mathrm{E}[\rho(\mathrm{r})] \tag{28}
\end{equation*}
$$

By re-writing $\mathrm{E}[\rho(\mathrm{r})]$ as functionals of the electron density $\rho(\mathrm{r})$, one obtains:

$$
\begin{equation*}
\mathrm{E}_{0}\left(\rho_{0}\right]=\mathrm{T}\left[\rho_{0}\right]+\mathrm{E}_{\text {ee }}\left[\rho_{0}\right]+\mathrm{E}_{\text {ne }}\left[\rho_{0}\right] \tag{29}
\end{equation*}
$$

The terms $T\left[\rho_{0}\right]$ and $E_{e e}\left[\rho_{0}\right]$ in equation 29 are system independent, whereas $E_{n e}\left[\rho_{0}\right]$ represents the potential energy due to the attractive interaction between nuclei and electrons and it is system dependent. Equation 29 can be split into specific components as follows

$$
\begin{equation*}
\mathrm{E}[\rho(\mathrm{r})]=\mathrm{T}_{\mathrm{ni}}[\rho(\mathrm{r})]+\mathrm{V}_{\mathrm{ne}}[\rho(\mathrm{r})]+\mathrm{V}_{\mathrm{ee}}[\rho(\mathrm{r})]+\Delta \mathrm{T}[\rho(\mathrm{r})]+\Delta \mathrm{V}_{\mathrm{ee}}[\rho(\mathrm{r})] \tag{30}
\end{equation*}
$$

where: $\mathrm{T}_{\mathrm{n}}$ is the kinetic energy of non-interacting electrons
$\mathrm{V}_{\mathrm{ne}}$ is the potential energy corresponding to the nucleus-electron interaction
$\mathrm{V}_{\mathrm{ee}}$ is the potential energy corresponding to the electron-electron interaction
$\Delta \mathrm{T}$ is the change in kinetic energy
$\Delta \mathrm{V}_{\mathrm{ee}}$ is the change in potential energy of the electron-electron interaction
All these terms are written in equation 30 as functionals of the probability density.

### 2.3.4.2. The Hohenberg and Kohn theorem

Hohenberg and Kohn developed two theorems. The first Hohenberg-Kohn theorem considers the ground state energy generated from the Hohenberg-Kohn functional when the ground state electron density is specified $[74,75,80]$. The second Hohenberg-Kohn theorem considers the ground state electron density and any guess electron density, and uses the variational principle. The first three terms in equation 30 form the Hohenberg-Kohn functional ( $\mathrm{F}_{\mathrm{HK}}\left[\rho_{0}\right]$ ), and they are system independent, while the last two terms are system dependent.

$$
\begin{equation*}
\left.\mathrm{F}_{\mathrm{HK}}\left[\rho_{0}\right]\right)=\mathrm{T}_{\mathrm{ni}}[\rho(\mathrm{r})]+\mathrm{V}_{\mathrm{ne}}[\rho(\mathrm{r})]+\mathrm{V}_{\mathrm{ee}}[\rho(\mathrm{r})] \tag{31}
\end{equation*}
$$

The guess electron density [ $\rho_{\text {trial }}$ ] results in an external potential giving a higher energy value than that of the ground state electron density

$$
\begin{equation*}
\mathrm{E}\left[\rho_{\text {trial }}\right]=\mathrm{T}\left[\rho_{\text {trial }}\right]+\mathrm{E}_{\text {ee }}\left[\rho_{\text {trial }}\right]+\mathrm{E}_{\mathrm{ne}}\left[\rho_{\text {trial }}\right] \geq \mathrm{E}_{0} \tag{32}
\end{equation*}
$$

The application of DFT within the Hohenberg-Kohn approximation failed because the kinetic energy expression from the Hohenberg-Kohn functional was not well established.

### 2.3.4.3. Kohn and Sham method

Kohn and Sham develop a method yielding the Kohn-Sham equations. The theory focused on a system of non-interacting electrons (in general, the wavefunction and electron density of noninteracting electrons differ from those of interacting electrons). This approach includes the construction of a non-interacting system in a way that the density is the same as that of the interacting electrons. After discovering a correspondence of the Slater determinant which approximates the N -electron wavefunction with the true wavefunction for a non-interacting electron system from the HF approximation, they could conclude that [77]

$$
\begin{equation*}
\mathrm{T}_{\mathrm{HF}}=\left\langle\chi_{i}\right| \nabla^{2}\left|\chi_{\mathrm{i}}\right\rangle \tag{33}
\end{equation*}
$$

where $\chi_{\mathrm{i}}$ are the spinorbitals
$\mathrm{T}_{\mathrm{HF}}$ is the HF approximation
The ground state wavefunction can then be expressed using the Slater determinant $\Theta_{s}$.

$$
\Theta_{\mathrm{s}}=\frac{1}{\sqrt{\mathrm{~N}!}}\left[\begin{array}{cccc}
\varphi_{1}\left(\vec{x}_{1}\right) & \varphi_{2}\left(\vec{x}_{1}\right) & \cdots & \varphi_{N}\left(\vec{x}_{1}\right)  \tag{34}\\
\varphi_{1}\left(\vec{x}_{2}\right) & \varphi_{2}\left(\vec{x}_{2}\right) & \cdots & \varphi_{N}\left(\vec{x}_{2}\right) \\
\vdots & \vdots & \ddots & \vdots \\
\varphi_{1}\left(\vec{x}_{N}\right) & \varphi_{2}\left(\vec{x}_{N}\right) & \cdots & \varphi_{N}\left(\vec{x}_{N}\right)
\end{array}\right]
$$

The orbitals $\left(\varphi_{i}\right)$ in the Kohn-Sham theory are similar to those considered in the HF theory, and are related to the eigenvalue, $\varepsilon_{i}$, through the eigenvalue equation:

$$
\begin{equation*}
\hat{f}^{K S} \varphi_{i}=\varepsilon_{i} \varphi_{i} \tag{35}
\end{equation*}
$$

where $\hat{f}^{K S}$ is the Kohn-Sham operator, which contains the effective potential $V_{S}(\vec{r})$ :

$$
\begin{equation*}
\hat{f}^{K S}=\frac{1}{2} \nabla^{2}+V_{S}(\vec{r}) \tag{36}
\end{equation*}
$$

Consequently, the Hohenberg-Kohn function within the Kohn-Sham approach can be written as

$$
\begin{equation*}
\mathrm{E}_{\mathrm{DFT}}[\rho]=\mathrm{T}_{\mathrm{s}}[\rho]+\mathrm{E}_{\mathrm{ne}}[\rho]+\mathrm{J}[\rho]+\mathrm{E}_{\mathrm{xc}}[\rho] \tag{37}
\end{equation*}
$$

where: $T_{s}[\rho]$ represent the kinetic energy of non-interacting electrons
$\mathrm{E}_{\mathrm{ne}}[\rho]$ represent potential nucleus-electron interaction potential energy
$\mathrm{J}[\rho]$ is the electron-electron interaction potential energy
$\mathrm{E}_{\mathrm{xc}}[\rho]$ is the exchange correlation energy
$\mathrm{E}_{\mathrm{xc}}[\rho]$ is calculated with an exchange-correlation functional and takes into account part of the electron correlation energy [74-80].

### 2.3.4.4. DFT functionals

The DFT method is focused towards the design of functionals which relate the electron density to the energy of the system. These functionals are classified based on their level of sophistication. The simplest functional is the LDA (Local Density Approximation), which is based on the assumption that the exchange correlation energy at any point in space is the only function of the electron on that point in space [81]. Consequently, LDA functional systems can be represented by a homogenous electron gas of the same density [82, 83]. Another functional is the GGA (Generalized Gradient Approximation) method which depend on both the electron density and the gradient. Since most molecular systems are spatially inhomogeneous and are different compared to a homogeneous electron gas, GGA is considered a significant improvement with respect to LDA.

Meta-GGA methods, which are methods which incorporate the kinetic energy density, and the hybrid density functionals combining the exchange-correlation of GGA with some level of HF exchange, have been developed. The hybrid functionals include the dependence on the kinetic energy density. One of the most commonly used hybrid functionals in quantum chemistry is the exchange correlation functional, B3LYP [84-87].

### 2.4. Molecular properties considered in this work

### 2.4.1. Conformers' relative energies

In the conformational study of molecules, it is interesting to compare the energy of the conformers whenever a molecule has more than one conformer). The outputs give the energies in Hartree, and these values are not convenient for comparisons to use in analysis. The easiest way to compare the energies of the conformers is by considering their relative energies. This is done by assigning zero value to the energy of the lowest energy conformer and considering the differences of the other energy values with respect to it. These differences are the relative energies of the individual conformers. Because of the way in which they are calculated, relative energies are always positive.

### 2.4.2. Vibrational frequencies and thermodynamic properties

In a molecule, different types of motions are possible and can influence its energy and physical properties [88, 89]. The motions comprise:

- translational motion: concerns the motion of the whole molecule in space
- rotational motion: concerns the rotation of molecules around the three axes $(x, y, z)$ in space
- vibrational motion: it is related to the periodic motion of the atoms within a molecule.

These motions are a major contribution to the energy of the molecule [50, 89]. Their contributions sum up and yield the thermal energy $\left(\mathrm{E}_{\mathrm{th}}\right)$ of a molecule

$$
\begin{equation*}
\mathrm{E}_{\mathrm{th}}=\varepsilon^{\mathrm{T}}+\varepsilon^{\mathrm{R}}+\varepsilon^{\mathrm{V}} \tag{38}
\end{equation*}
$$

where $\varepsilon^{\mathrm{T}}$ corresponds to the translation contribution
$\varepsilon^{\mathrm{R}}$ corresponds to the rotational contribution
$\varepsilon^{\mathrm{V}}$ corresponds to the vibrational contribution

The total energy of the molecule (E) is given by the sum of the thermal energy and the electronic energy $\left(\varepsilon^{\mathrm{E}}\right)$ and can be written as

$$
\begin{equation*}
\mathrm{E}=\varepsilon^{\mathrm{T}}+\varepsilon^{\mathrm{R}}+\varepsilon^{\mathrm{V}}+\varepsilon^{\mathrm{E}} \tag{39}
\end{equation*}
$$

The degrees of freedom of a particle are defined as the number of variables needed to give a complete description of its motion. They are expressed in terms of the coordinates in space ( $\mathrm{x}, \mathrm{y}$, z). The motion of an atom moving in three-dimensions (translational motion) is described by three coordinates; therefore, the atom will have three degrees of freedom. For a molecule with N atoms, the total number of degrees of freedom is 3 N , because each atom has 3 degrees of freedom. Three of these 3 N degrees of freedom correspond to the translational motion of the molecule, which is the motion of the whole molecule in space. To know the degrees of freedom for rotational motion, we need to distinguish whether a molecule is linear or non-linear. For a non-linear molecule, there are three degrees of freedom for rotation because rotation is possible around all the three axes. For a linear molecule, the rotation around the molecular axis is not allowed; therefore, there are two degrees of freedom for rotation.

The degrees of freedom for vibrational motion are given by

Vibrational motion degrees of freedom $=$ total degrees of freedom - translational degrees of freedom - rotational degrees of freedom

Therefore, the vibrational degrees of freedom are $3 \mathrm{~N}-6$ for non-linear molecules and $3 \mathrm{~N}-5$ linear molecules [90].

Vibrational motions of a molecule can occur in all phases of matter (solid, liquid and gas). The simplest description for a molecular system with more than one vibrational mode considers the vibrations of a tri-atomic molecule, i.e. a molecule with only two bonds. The type of vibrations possible are

- symmetric stretching: the two bond lengths alternatingly increase and decrease simultaneously by the same amount
- asymmetric stretching: alternatingly, one bond lengths increase as the other decreases by the same amount
- bending: the bond angle between the two bonds changes

As the number of atoms increases, the type and number of vibrations also increases. Vibrational motions can also change the shape of a molecule. The lower energy vibrational motions can also change the shape of the benzene ring.

A molecular vibration is excited when a molecule absorbs a quantum of energy corresponding to the given vibrational frequency [91, 92]. Since the vibrations in a molecule are periodic motions, the harmonic approximations (harmonic oscillator) is the simplest approach. Using this approximation, the motion in a normal vibration can be described as a simple harmonic motion. The energy of a particle oscillating harmonically has two components, the kinetic energy and the potential energy. The vibrational potential energy (V) is a quadratic function with respect to the atomic displacement [50, 52].

$$
\begin{equation*}
V=\frac{1}{2} k x^{2} \tag{41}
\end{equation*}
$$

where: k is the restoring force constant

$$
x \text { is the displacement along the } \mathrm{x} \text { direction }
$$

Therefore, the Schrödinger equation for a particle with a mass $m$ oscillating harmonically is given by the equation

$$
\begin{equation*}
-\frac{h^{2}}{2 m} \frac{\partial^{2} \psi}{\partial x^{2}}+\frac{1}{2} k x^{2} \psi=\mathrm{E} \psi \tag{42}
\end{equation*}
$$

The first term on the left-hand side corresponds to the kinetic energy of the particle and the second term to its potential energy. By solving the Schrödinger equation, we obtain the energy values, given by

$$
\begin{equation*}
E_{v}=\left(v+\frac{1}{2}\right) \hbar \omega \tag{43}
\end{equation*}
$$

where $v$ is the vibrational quantum number
$\omega$ is related to the force constant by the equation

$$
\begin{equation*}
\omega=\frac{1}{2 \pi} \sqrt{\frac{k}{m}} \tag{44}
\end{equation*}
$$

Considering the harmonic oscillator potential (figure 2.6), the spacing between the energy levels is constant and is equal to $\hbar \omega$. This is one of the limitations of the harmonic approximation, which would imply that all the transitions between two neighboring levels occur at the same frequency $\left(\Delta E_{v+1, v}=\hbar \omega\right)$ [52]. Anharmonic corrections may be introduced to improve the results with respect to the harmonic oscillator. A frequent approximation is the Morse potential, which also takes into consideration bond dissociation. As the quantum number increases, the spacing between neighboring energy levels decreases. The Morse potential is a better representation of the potential energy for the vibrations in a molecule.

Strectching motion of a bond

Figure 2.6. Harmonic oscillator potential and the Morse potential [93]

### 2.4.3. Zero-point corrected energy

The frequency calculations also give us the zero-point energy (ZPE), that is the difference between the lowest part of the potential $(\mathrm{V}=0)$ and the first vibrational energy level (corresponding to $\mathrm{v}=$ 0 ). This energy difference is equal to $\frac{1}{2} \hbar \omega$ for the harmonic oscillator. This correction must be included to get the total energy of the molecule. When we consider the energy with this correction, we call it the zero-point corrected energy [52, 94, 95].

### 2.4.4. Molecular orbitals (HOMO and LUMO)

Molecular orbitals are the solutions of the Schrödinger equations and are built with the LCAO approximations (section 2.3.3.2). Molecular orbitals can be either bonding or antibonding [96, 52]. A bonding molecular orbital, when occupied, decreases the energy of the system with respect to the separated atoms. An antibonding molecular orbital, when occupied, increases the energy of the system with respect to the separated atoms. Therefore, the bonding molecular orbital has a stabilizing effect on the system, when they are occupied, and the antibonding molecular orbital has a destabilizing effect on the system.
Two molecular orbitals are particularly important for the description of a molecule because they relate to its properties: the Highest Occupied Molecular Orbital (HOMO) and the Lowest Unoccupied Molecular Orbital (LUMO). The energy difference between these molecular orbitals (HOMO-LUMO energy gap) is related to some molecular properties, including the reactivity of the molecules [97-100]. The most stable molecules have a higher energy gap, and the less stable molecules have a smaller energy gap. Molecules with smaller energy gaps may undergo chemical reactions more easily. The energy gap also relates to the ability of a substance to conduct electric current; a smaller gap is related to better conductivity [101].

### 2.4.5. Dipole moments

The electric dipole moment $(\mu)$ is defined for a pair of opposite charges of magnitude q , as the magnitude of the charge multiplied by the distance between them. The direction of the resulting dipole moment vector $(\vec{\mu})$ is toward the positive charge [102, 103]. A bond is polar when the two bonded atoms have different electronegativities. Each polar bond has a dipole moment. There is a dipole moment for the whole molecule if the sum of the vectors of all the dipole moments of the
bonds is not zero. The sum is given by the equation.

$$
\begin{equation*}
\vec{\mu}=\sum_{i} q_{i} \vec{r}_{i} \tag{45}
\end{equation*}
$$

where: $\vec{\mu}$ is the resulting dipole moment vector of the molecule
$q_{i} \vec{r}_{i}$ is the dipole moment of bond i

Water molecule

Carbon dioxide

Figure 2.7. Dipole moments of individual bonds and dipole moment of the water molecule and the carbon dioxide molecule.

The sum of the vectors depends on their mutual orientations. Figure 2.7 shows the case of water and the case of carbon dioxide $\left(\mathrm{CO}_{2}\right)$. Both molecules have two polar bonds, but, in the water molecule, the sum of the vectors is not zero because the two vectors form a non-zero angle, whereas in the $\mathrm{CO}_{2}$ molecule, the sum of the vectors is zero because the two vectors are opposite and equal (angle equal to $180^{\circ}$ ) [103, 104].

### 2.4.6. Hydrogen bonds

Hydrogen bond is considered as a type of dipole-dipole attraction which occurs when a hydrogen atom $(\mathrm{H})$ is bonded to a more electronegative and small-size atom $(\mathrm{X})$, and another electronegative atom is available in the vicinity (100-102). A hydrogen bond can be illustrated as an interaction between a donor $\mathrm{X}-\mathrm{H}$ and an acceptor Y (figure 2.8). X can be an electronegative atom such as oxygen $(\mathrm{O})$, nitrogen $(\mathrm{N})$ and fluorine $(\mathrm{F})$ but, in some instances, it can be a carbon $(\mathrm{C})$ atom. The acceptor Y can be an electronegative atom such as $\mathrm{O}, \mathrm{N}$ or F . The Y atom usually has at least one electron pair available. Hydrogen bonds are usually denoted by denoted segments.

Figure 2.8. Illustration of a hydrogen bond

Different hydrogen bonds have different characteristics according to the nature of X and Y , and also to the molecular context. We usually describe the hydrogen bonds through their parameters: bond length, donor $\cdots$ acceptor distance ( $\mathrm{X} \cdots \mathrm{Y}$ ), and XĤY bond angle. The parameters also provide information about the hydrogen bond strength. The stronger hydrogen bonds are characterized by $1.2-1.5 \AA \mathrm{H} \cdots \mathrm{Y}$ bond length, with $2.2-2.5 \AA \mathrm{X} \cdots \mathrm{Y}$ donor $\cdots$ acceptor distance, and $170-180^{\circ} \mathrm{XH} \mathrm{Y}$ bond angles. Moderate hydrogen bonds are characterized by $1.5-2.2 \AA \mathrm{H} \cdots \mathrm{Y}$ bond length, with $2.5-3.2 \AA \mathrm{X} \cdots \mathrm{Y}$ donor $\cdots$ acceptor distance, and $130-150^{\circ} \mathrm{XHY}$ bond angles. Weaker hydrogen bonds are characterized by 2.2-3.2 $\AA \mathrm{H} \cdots \mathrm{Y}$ bond length, with 3.2-4.0 $\AA \mathrm{X} \cdots \mathrm{Y}$ donor $\cdots$ acceptor distance, and $90-120^{\circ} \mathrm{XHY}$ bond angles [105-107]. An example of a weak hydrogen is shown in figure 2.9. The $\mathrm{sp}^{2} \mathrm{O}$ of the COOH group forms a hydrogen bond with the hydrogen on the OH group; this hydrogen bond is weak because of the small OHO bond angle [108].

Figure 2.9. The weak hydrogen bond present in the carboxylic $(\mathrm{COOH})$ group. The acetic acid molecule is selected as illustrative example.

There are two types of hydrogen bonds: intermolecular hydrogen bonds and intramolecular hydrogen bonds [109].

Intermolecular hydrogen bonds are hydrogen bonds which occurs between separate molecules. The donor belongs to one molecule and the acceptor belongs to another molecule. An example is
given by a hydrogen bond between two water molecules (figure 2.10).

Intramolecular hydrogen bonds (IHBs) are hydrogen bonds which occur within a molecule. Both the donor and the acceptor belong to the same molecule. For such a hydrogen bond to form, the donor and the acceptor atoms must be able to come close to each other. An example is the hydrogen bond present in the salicylaldehyde molecule (Figure 2.10). IHBs are important in biomolecules, for example, proteins and DNA [109, 110]. It is important to consider the IHBs when studying a molecule because they stabilize a molecule and also influence its geometry. They are also particularly important for the study of biologically active molecule because they may be involved in the mechanism by which the biologically active molecules interact with the biological target .

Intermolecular hydrogen bond between two water molecules

Intramolecular hydrogen bond in salicylaldehyde [111]

Figure 2.10. Examples of intermolecular and intramolecular hydrogen bonds

There are instances in which two hydrogen bonds share the same donor or acceptor; such bonds are termed bifurcated hydrogen bonds [112, 113]. For example, one hydrogen bond donor can be bonded to two hydrogen bond acceptors (e.g. $\mathrm{C}=\mathrm{O} \cdots \mathrm{H} \cdots \mathrm{O}=\mathrm{C}$ ); this is called a bifurcation on the hydrogen. Figure 2.11 shows an example of hydrogen bonds bifurcated on the hydrogen atom. It may also happen that two hydrogen bond donors are bonded to the same hydrogen bond acceptor (e.g., $\mathrm{N}-\mathrm{H} \cdots \mathrm{O} \cdots \mathrm{H}-\mathrm{N}$ ); this is called a bifurcation on the oxygen atom. In some cases, the acceptor may be over coordinated.

Figure 2.11. Example of hydrogen bonds bifurcated on the hydrogen atom.
The H atom bonded to the N which is bonded to the S atom is IHB donor to two O atoms - the O atom bonded to the S atom and the O atom bonded to the C atom between the two N atoms. The two IHBs are represented by dashed segments.

### 2.4.7. Red shift in the vibrational frequencies of the donor

The red shift is the decrease in the IR vibrational frequency of the bonds involved in the hydrogen bonding. The red shift is related to the elongation of the $\mathrm{X}-\mathrm{H}$ (proton donor) bond length in the $\mathrm{X}-\mathrm{H} \cdots \mathrm{Y}$ system. The red shift is correlated to the strength of an IHB [114].

## Chapter 3

## Literature review

This chapter presents information about diabetes as a disease and about the sulfonylureas molecules which are used for its treatment.

### 3.1. Diabetes mellitus

Diabetes mellitus $[1,115,116]$, commonly referred to as diabetes, is a group of metabolic diseases characterized by high blood sugar (glucose) levels that result from defects in insulin secretion, or in its action, or both [1, 117]. Insulin is a hormone that the body needs to get glucose from the bloodstream into the cells of the body [118]. Diabetes mellitus was first (in the ancient world) identified as a disease associated with "sweet urine" and excessive muscle loss. The occurrence of diabetes is rapidly increasing in recent times and diabetes has become a worldwide health threat in the past decades. According to a statistical report, it is estimated that 382 million people worldwide, or $8.3 \%$ of the adult population, had diabetes in 2013; if these trends continue, the number will rise to 592 million by 2035 [117]. Furthermore, diabetes creates a favorable situation for the development of cardiovascular diseases, which are currently the first cause of death worldwide.

### 3.1.1. Different types of diabetes

There are three main types of diabetes, namely, type 1 diabetes, type 2 diabetes and gestational diabetes.

### 3.1.1.1. Type 1 diabetes

Type 1 diabetes is usually diagnosed in children and young adults and was previously known as juvenile diabetes [1]. Only 5-10\% of diabetes cases are of this type. In this type of diabetes, the body does not produce insulin. People with type 1 diabetes rely on insulin injections or on continuous infusion of insulin via an insulin pump. There has been a rapid evolution in the care and treatment for people with type 1 diabetes, such as genetically engineered insulin and glucose
monitoring devices, to control the blood glucose levels and to prevent or delay the diabetes-related complications [119, 120].

Figure 3.1 outlines the various phenomena which are involved in type 1 diabetes. The process includes various stages. The carbohydrates entering the body with food are converted to glucose (stage 1). The glucose then enters the blood stream to help the pancreas in the production of insulin (stage 2). If the pancreas produces little or no insulin (stage 3), the insulin that gets into the bloodstream is insufficient (stage 4). Then, not enough glucose is removed from the bloodstream to the cells. As a consequence, glucose builds up in the bloodstream (stage 5), thus resulting in type 1 diabetes [117].

Figure 3.1. Phenomena involved in type 1 diabetes [117]

### 3.1.1.2. Type 2 diabetes

Type 2 diabetes constitutes the vast majority (about $90 \%$ ) of the cases of diabetes [115]. It is commonly diagnosed in the population over the age of 45 years [121, 122]; in recent decades, it is increasingly developing also in younger people, even children under 14 years of age. It is a long term metabolic disorder that is characterized by high blood sugar levels caused by lack of insulin, in turn due to insulin resistance. In the early stages of the disease, the insulin levels in the blood
are mostly normal or slightly elevated; at this early stage, people can usually manage their conditions so as to delay - and, in some cases, even prevent - the disease, by adopting a healthy lifestyle, including regular physical activities, healthy food intake and losing excess body weight [123]. However, at a later stage of the disease, patients become insulin-deficient and may require oral medications; eventually, when other medications fail to control the blood glucose level adequately, they need insulin injections. In the worst scenarios, diabetes may cause gangrene of the lower limbs, which results in the need for their amputation. It can also lead to blindness, and to heart and kidney failure.

### 3.1.1.3. Gestational diabetes

Gestational diabetes is a form of diabetes characterised by high glucose levels in the blood during the later stages of pregnancy [120, 124]. Gestational diabetes is said to affect about $4 \%$ of pregnancies worldwide and can cause complications to both mother and baby [1]. Gestational diabetes usually resolves after the delivery of the baby, but women with gestational diabetes and their children are at a higher risk of developing type 2 diabetes [124]. Approximately half of the women with a history of gestational diabetes have developed type 2 diabetes within five to ten years after delivery [125]. Since gestational diabetes can affect both mother and baby, it is important for it to be treated as early as possible. Treatments for gestational diabetes include special dietary plans and regular physical activities to keep normal blood glucose level, which are similar to those pregnant women should do [126]. In more serious cases, the treatment may also include daily blood glucose testing and insulin injections.

### 3.1.2. Diabetes in South Africa

According to a 2017 report based on the information released by Statistics South Africa on the causes of deaths in the country, there has been a significant increase in deaths due to diabetes [127]. The report says that the majority of people with diabetes have type 2 diabetes. The prevalence of type 2 diabetes was estimated at $4.5 \%$ in 2010 [128, 129]. Over the past years, diabetes moved from being the 5th biggest killer (in 2013) to be the second biggest killer in South Africa (responsible for $5.4 \%$ deaths in 2015, [130-132]) and the leading cause of death among
females. Diabetes was found to have been the number-one cause of death in the Western Cape Province. The reports suggest that in 2016 women were $36 \%$ more likely to die due to diabetes than from the combination of other causes [133]. Experts suggested that up to $7 \%$ of South Africans aged 21 to 79 ( 3.85 million people) had diabetes by then [129, 130]. The increase in the cases of people getting sick with diabetes is due to poor diet (unbalanced diet) and obesity. Excessive consumption of calories and sedentary lifestyles, and high consumption of soft and energy drinks, are also main contributors to the development of diabetes, because of their high sugar content [133].

Type 2 diabetes is said to be placing a large burden on the healthcare system. This is because of the costs associated with the management of diabetes, which may effectively require daily treatment and a regular monitoring, a healthy diet and lifestyle and diabetes-based education to ensure awareness [130]. The costs may also include hospital and medication costs and government provided disability grants. The health expenditure in relation to diabetes is said to be increasing yearly since 2010, and the costs are becoming alarming. A high presence of diabetes in the country can also affect work productivity in an indirect way, as healthy employees remain absent in order to care for sick relatives. Reports indicate that $76 \%$ of diabetes-related deaths occur amongst people below the age of 60 , which is said to be the economically productive population [131, 132].

### 3.1.3. Most common symptoms of diabetes

The symptoms may develop gradually, not in direct relationship to whether an individual has insulin resistance. The body may manage with lower insulin levels for a certain period, but some symptoms eventually begin to be noticed; these include [134-138]:

- Fatigue: the body may not be getting the needed energy from the consumed foods, which results in a person feeling tired;
- Extreme thirst: the tissues get dehydrated when there is too much glucose in the blood, because the body will often pull the fluids from the tissues to the blood in an attempt to keep the blood diluted and to also counteract the high glucose levels. Consequently, the dehydrated tissues will relay a message that more water is needed;
- Frequent urination: it is due to drinking a lot of water to stay hydrated; it is also an attempt by the body to get rid of the excess glucose through urination;
- Extreme hunger: due to the body's insulin resistance, the glucose is prevented from entering the muscles and providing energy; therefore, the muscles and other tissues will relay a hunger message even after the individual has eaten, because they are not getting the needed energy;
- Weight loss: when the body does not get the energy it needs from food, it breaks down the fat and the muscles in order to create some energy, and this results in weight loss;
- Infections: the body may experience frequent infections due the effects of type 2 diabetes. Bacteria are known to flourish when the levels of glucose in the blood are high, and this makes it difficult for the body to fight off infections;
- Slow wound healing: the functionality of the white blood cells, which are responsible for wound healing, is affected by the high levels of glucose in the blood; therefore, it may take longer for wounds to actually heal;
- Blurry vision: the body may pull fluids from the eyes in an attempt to counteract the high levels of glucose in the blood; this may cause problems with focusing, resulting in blurry vision.

### 3.1.4. Diabetes related complications

When diabetes is present in the body for many years, it can result in several complications including heart (cardiomyopathy) and kidney (nephropathy) diseases, diabetic eye diseases (including retinopathy), and problems to the nervous system (neuropathy) [115]. Some of these complications can become extremely damaging to the body if left untreated. For instance, retinopathy can result in blindness [139]. The interference of diabetes with wound healing may result in ulcerations, leading to amputations in the worst cases [140, 141].

### 3.1.4.1. Diabetic nephropathy

Diabetic nephropathy is a kidney disease which is as a result of diabetes [142]. It affects the kidney's ability to do their usual work of waste products and extra fluid removal from the body.

Diabetes affects the tiny blood vessels in the glomerulus, a key structure in the kidney composed of capillary blood vessels and critical for the filtration of blood to remove waste products [142147]. Diabetic nephropathy is a leading cause of kidney failure worldwide. More than $40 \%$ of the people with diabetes are likely to develop diabetic nephropathy.

The association of kidney disease and diabetes is worse than the presence of kidney diseases alone. This is because there is a high possibility that people with diabetes have also other diabetes-related medical conditions such as high blood pressure, high cholesterol, blood vessel diseases, and progressively impaired kidney function. People with diabetes are also more likely to have kidneyrelated diseases such as nerve damage to the bladder and bladder infections [146, 147]. When diabetic nephropathy is severe, an individual may experience kidney failure (end-stage renal disease) and, as a result, he/she may require kidney dialysis or worse, a kidney transplant [148]. It is said that about 1 in 4 women and 1 in 5 men with type 2 diabetes develops diabetic nephropathy.

### 3.1.4.2. Diabetic cardiomyopathy

Diabetic cardiomyopathy is a major cause of heart failure among people with diabetes. It is one of the cardiovascular diseases which are leading cause of death amongst diabetic patients [146, 149]. People with diabetes are 2-5 times more likely to develop heart failure as compared to non-diabetic patients [150, 151]. Diabetic cardiomyopathy is known as a specific form of heart disease which is promoted by resistance in the heart tissue to the metabolic actions of insulin (insulin resistance). It is defined as the presence of abnormal cardiac structure and performance in the absence of coronary artery disease, hypertension, and significant valvular disease [152, 153].

### 3.1.4.3. Diabetic eye diseases

Diabetic eye diseases are a group of eye conditions affecting people with diabetes [154, 155]. These conditions may affect different parts of the eye including the retina, macula, lens and the optic nerve. They are often differentiated based on the parts of the eye that is mostly affected. They include diabetic retinopathy, diabetic macular oedema (DME), diabetic cataract and glaucoma. They can potentially cause severe vision loss and blindness.

### 3.1.4.3.1. Diabetic retinopathy

Diabetic retinopathy is a very serious sight-threatening complication of diabetes [156, 157]. It is the most common cause of the loss in vision, and a leading cause of blindness and vision impairment, amongst the people with diabetes and the working-age adults. It affects the retina -a light sensitive tissue lining the back of the eye, which is responsible for detecting and converting light to signals sent through the optic nerve to the brain. Retinopathy is a result of the damage caused by diabetes on the tiny blood vessels located in the retina [158]. The damage to these blood vessels is also associated with chronically high levels of glucose in the blood. As a result, the retinal blood vessels may end up leaking fluid into the macula, which is the part of the retina enabling us to see different colours and fine details and, therefore, is the part responsible for clear vision. The macula may swell because of the excess fluid, and this results in blurred vision.

New blood vessels may form on the surface of the retina as an attempt to improve the blood circulation. Since these new blood vessels are very fragile, they can possibly bleed into the back of the eye resulting in the blockage of vision [159, 160].

Diabetic retinopathy can be classified into two types: non-proliferative and proliferative. Nonproliferative diabetic retinopathy (NPDR) is the earlier stage of the disease, where the symptoms are mild. During this stage, the tiny blood vessels in the retina are weak. There are tiny bulges in the blood vessels (microaneurysms) which may begin leaking fluid into the retina. Due to this leakage, the macula may swell.

Proliferative diabetic retinopathy (PDR) is the most advanced stage of the disease, where there are circulation problems which can deprive the retina of oxygen. Cosequently, there is a growth of new and fragile tiny blood vessels in the retina and into the vitreous fluid (the gel-like fluid filling the back of the eye). These tiny blood vessels may leak blood into the vitreous, resulting in a clouded vision [159-162].

## Diabetic Retinopathy

Figure 3.2: Difference between a healthy eye and a diabetic eye [1163].

Figure 3.2 shows the difference between a heathy eye and an eye affected by diabetic retinopathy and other diabetic eye conditions. It also shows the presence of the abnormal tiny blood vessels which are most likely to form on the surface of the retina in an attempt to increase the circulation of blood.

### 3.1.4.3.2. Diabetic macular edema

Diabetic macular oedema (DME) is characterized by the presence of retinal thickening or the accumulation of fluid in the macula from the damaged blood vessels. DME is the most common cause of vision loss among the people with diabetic retinopathy, and it is said that about half of the people with diabetic retinopathy may develop DME [164]. It is most likely to occur in a worsened case of diabetic retinopathy, but can also occur in any stage of the disease [156, 162, 165].

### 3.1.4.3.3. Glaucoma

Glaucoma is a group of eye conditions which damages the optic nerve (bundle of nerve fibres connecting the eye and the brain). It is also associated with elevated pressure inside the eye [158, 166]. Glaucoma is known to affects adults, but its risk is doubled for people with diabetes.

### 3.1.4.3.4. Cataract

Cataract is the clouding of the eye's lens. It is more likely to develop in adults with diabetes than in those without it. It can also develop in people with diabetes at a younger age than for people without diabetes [167, 168].

### 3.1.4.4. Diabetic neuropathy

Diabetic neuropathy is a very serious and most common complication of diabetes. It is a type of nerve damage which can occur among the people with diabetes [169]. It most commonly affects the nerves of the legs and feet. There are many symptoms of diabetic neuropathy, depending on the nerves damaged, and some damages to the nerves can lead to disability in the worst cases [170].

### 3.1.4.4.1. Types of diabetic neuropathy

There are four different types of diabetic neuropathy, and it is highly possible for a person to have more than one type. The symptoms develop gradually; therefore, an individual may not notice the damage until a considerable damage to the nerves has already occurred.

These diabetic neuropathy types differ according to the part of the body where the affected nerves are [169-171]:

- Peripheral neuropathy is the most common type of neuropathy and it mostly affects first the legs and feet and then the hands and arms. Its symptoms include tingling, sharp pains and increased insensitivity. It may lead to the need for amputation.
- Autonomic neuropathy affects the autonomic nervous system, which is the one that controls the heart, stomach, intestines, bladder and the eyes. The nerves in any of these
areas may be affected, resulting in bladder problems, persons' lack of awareness of the low blood sugar levels and increased heart rate.
- Radiculoplexus neuropathy affects the nerves in the hips, thighs and legs. It is most common among people with type 2 diabetes and adults. It usually affects only one side of the body.
- Mononeuropathy (also referred to as focal neuropathy), is the damage due to diabetes to a specific nerve in the face, middle body and the legs. It is most common among adults and can cause severe pain but not long-term problems. It can also cause problems in the eyes resulting in double vision.

### 3.1.4.4.2. Complications related to diabetic neuropathy

Diabetic neuropathy may lead to severe complications. They are outlined in the next paragraphs.

### 3.1.4.4.2.1. Amputations (mostly loss of a foot or leg)

Diabetes has been found to be one of the leading causes of amputation of the lower limbs throughout the world [115, 141]. Charity Diabetes UK noted that foot problems are the most frequent reasons for hospitalization amongst patients with diabetes [172]. Reports suggests that people with diabetes are up to 30 times more likely to undergo amputations than those who don't have it [172-175]. Amputations are more common among the elderly and their rate increases with age [141].

Diabetes can lead to peripheral artery disease (PAD) due to elevated blood glucose levels [176, 177]. PAD causes the narrowing of the blood vessels and also a reduction in the amount of blood flowing to the legs and feet [178]. This may result in the nerve damage known as peripheral neuropathy and can prevent a person from feeling pain. This means that individuals may not realize if they have a wound or ulcer on the feet. Continued pressure on the affected area can then cause the ulcer to grow and become infected [177]. Reduced blood flow can slow wound healing and make the body less effective in fighting infections, which results in healing failure for that wound. Tissue damage or gangrene may also inset, and the existing infection may spread to the bones. If the infection does not respond to treatment, or if it is irreparable, then amputation may be necessary. Amputations of toes, feet, and lower legs are the most common [178].

### 3.1.4.4.2.2. Other complications

Urinary tract infections and urinary incontinence: Damage to the nerves that control the bladder may cause an individual to be unable to empty the bladder fully. There can also be a buildup of bacteria in the bladder and kidneys, causing urinary tract infections. An individual may also be unable to feel the need to urinate or also be unable to control the muscles that release urine which may results in the leakage of urine (incontinence) [171].

Digestive problems: If the nerves in the digestive tract are damaged, an individual may experience diarrhoea or constipation. The nerve damage due to diabetes cause gastroparesis, which is a condition in which the stomach is very slow to empty wastes or even fails to do it. As a consequence, there might be an interference with the digestion, which may severely affect the levels of glucose in the blood. The symptoms may include vomiting and bloating.

Joint damage: Diabetes-related nerve damage can also cause the joints to deteriorate [179]. The deterioration usually occurs in the feet and affects the small joints. The symptoms may include sensitivity loss and swelling, instability and deformity of joints.

Increased or decreased sweating: The nerve damage due to diabetes can cause disruption of the functionality of the sweat glands; therefore, the body may have difficulties controlling the temperature properly. People with autonomic neuropathy may experience excessive sweating during the night or even when they are eating. Too little or no sweating at all may be lifethreatening [169, 170].

Sharp drops in blood pressure: If the nerves that controls the flow of blood are damaged due to diabetes, the body's ability to adjust blood pressure may be affected. This may result in sharp drops in the blood pressure when an individual stands and may cause dizziness and even fainting [170].

### 3.1.5. Insulin

### 3.1.5.1. The action of insulin

Insulin is a major metabolism-regulating hormone which is secreted by $\beta$-cells in the pancreas
[180]. The major function of insulin is that of countering the actions of some of the hormones which generate hyperglycaemia and also maintaining low levels of glucose in the blood. In addition to its role in regulating glucose metabolism, insulin stimulates lipogenesis and increases the transportation of amino acids into cells [181]. Insulin also has a role in promoting the storage of dietary calories, thus lowering the circulating levels of glucose coming from carbohydrate throughout the whole body.

Figure 3.3 outlines some of the phenomena that occur in the body and some pathways involving insulin. The liver, skeletal muscles, and adipose tissues are the main target tissues of insulin. Insulin increases the activity of enzymes enhancing glycogen, lipid and protein synthesis in the liver. At the same time, insulin also suppresses the activity of enzymes catalyzing gluconeogenesis and glycogenolysis, which break down the glycogen stored in the liver and muscles into glucose [181, 182]. Insulin stimulates the uptake of glucose, fatty acids and amino acids from the blood, permitting synthesis and storage of glycogen, carbohydrates, lipids, and proteins in the skeletal muscles.

## Blood glucose control

Blood glucose concentration is controlled by the release of hormones from the pancreas

Figure 3.3. Blood glucose control including the actions of insulin and glucagon and their pathways [183].

Insulin also promotes lipogenesis to store substrates and inhibits lipolysis (breakdown and release of fatty acids by adipose tissue) in adipose tissue. Most of the glucose ( $80 \%$ ) that is taken up by peripheral tissues is utilized by muscles with a relatively smaller amount being turned into fat or deposited in the liver [182, 184].

### 3.1.5.2. Insulin resistances

Insulin resistance is a condition in which the cells in the body are resistant to the effects of insulin; this means that there is a reduction in the response to a given amount of insulin [185]. As a consequence, higher amount of insulin will be required for it to affect the body properly, the pancreas then compensates by producing even more insulin. The resistance may be caused by genetic factors and also some medications can be contributing factors, and is common in people with obesity and during pregnancy. It may occur in response to the body's own insulin or when insulin is administered by injection.

### 3.1.6. Classification of antidiabetic drugs/agents

Different types of medicines involved in the treatment of diabetes are referred to as antidiabetic agents [186]. These agents aim at reducing the blood sugar levels to an acceptable range and relieving symptoms of diabetes such as thirst, excessive urination, and ketoacidosis [187]. Antidiabetic agents also prevent or slow down the development of diabetic complications, including neuropathy and retinopathy [188].

Table 3.1 outlines the main classification of known antidiabetic agents, including the known drugs for each class and their principal modes of action. Different classes of antidiabetic drugs have different modes of action and are applied in the treatment of different types of diabetes [186-189]. The current work focusses on sulfonylureas.

Table 3.1: Classes of antidiabetic medications against type 2 diabetes

| Class | Examples | Principal mode of action |
| :--- | :--- | :--- |
| Sulfonylureas | Glimepiride, Glipizide <br> Gliclazide, Tolbutamide, <br> Glyburide, chlorpropamide | Stimulate insulin secretion |
| Thiazolidinediones | Pioglitazone, Rosiglitazone | Increase insulin action |
| Alpha-glucosidase <br> inhibitors | Acarbose, Miglitol | Slow down the rate of carbohydrate ingestion |
| Biguanides | Metformin, Buformin, <br> Phenformin | Improve insulin action |
| Amylin analogs | Pramilintide | Decrease glucose levels |
| Sodium Glucose CO - <br> Transporter 2 <br> inhibitors | Remogliflozin, Dapagliflozin | Reduce glucose reabsorption in the proximal <br> renal tubules and lowers renal glucose <br> threshold |

### 3.2. Sulfonylureas

### 3.2.1. Description of Sulfonylureas

Sulfonylureas are a class of organic compounds used in medicine as antidiabetic drugs [190]. Figure 3.4 shows their general molecular structure. It comprises a benzene ring with two mutually para substituents: an $\mathrm{R}^{1}$ group and the thiourea group (a sulphonyl group to which a urea group is attached). A substituent $R^{2}$ may be attached to the urea group. Different molecules differ by the nature of $\mathrm{R}^{1}$ and $\mathrm{R}^{2}$, which can be either cyclic or acyclic organic groups [191].

Figure 3.4. General structure of sulfonylureas molecules

The sulfonylureas molecules are further divided in two categories, namely, first-generation and second-generation sulfonylureas molecules [192]. The main difference between the two classes is the way in which they bind to the sulfonyl receptor, with the second generation binding more tightly and thus requiring a lower dose to stimulate the secretion of the same amount of insulin [2, 193]. First generation sulfonylureas include chlorpropamide and tolbutamide (figure 3.5). The second-generation sulfonylureas include glipizide and glimepiride (figure 3.6) [192].

Chlorpropamide

Tolbutamide

Figure 3.5: Examples of first-generation sulfonylureas

Glipizide

Glimepiride

### 3.2.2. Mechanism of action of sulfonylureas

Sulfonylureas are widely used in the management of type 2 diabetes mellitus, when it is still possible to manage it without insulin injections. Sulfonylureas lower blood glucose levels by stimulating insulin release from the $\beta$-cells of the pancreas [194]. Their action depends on the presence of functioning $\beta$-cells; so, they are ineffective where there is absolute deficiency of insulin production, such as in type 1 diabetes, or in post-pancreatectomy situations.

Sulfonylureas stimulate insulin release by blocking ATP (adenosine triphosphate) sensitive potassium channels in the $\beta$-cells, thus reducing potassium permeability. They bind to an ATPdependent $\mathrm{K}^{+}$(KATP) channel on the cell membranes of pancreatic $\beta$-cells, thus inhibiting a tonic, hyperpolarizing outflux of potassium, which would cause the electric potential over the membrane to become more positive. This causes depolarization of the cell membrane and increases calcium entry [195]. The rise in intracellular calcium leads to increased fusion of insulin granules with the cell membrane and, therefore, increases the secretion of insulin.

Sulfonylureas can also sensitize $\beta$-cells to glucose, in such a way that they limit the production of glucose in the liver in order to decrease lipolysis (breakdown and release of fatty acids by adipose tissue) and also decrease the clearance of insulin by the liver [196, 197]. Moreover, they inhibit glucagon secretion and sensitize target tissues to the action of insulin. These drugs rapidly lower the blood sugar level but also run a risk of causing hypoglycaemia.

## Chapter 4

## Results

This chapter presents the results of the calculations on the sulfonylureas molecules considered in this study. The chapter analyses the results according to selected criteria. The conclusions will then be summarised in chapter 5 .

### 4.1. Molecules considered

### 4.1.1. Description of the molecules considered

The molecules considered in this work are sulfonylureas (section 3.2) with specific characteristics. Figure 4.1. shows the general structure of the considered sulfonylureas molecules and the atom numbering for the atoms that are present in all these molecules. It is considered important to give the same numbers to the atoms present in the same positions in all the molecules to facilitate descriptions and comparisons.

All the molecules have the sulfonylurea moiety attached to a benzene ring (a group typical of sulfonylureas molecules) and an oxygen atom (O7) attached to the benzene ring in para position with respect to the sulfonylurea moiety; furthermore, a group R is attached to the outer nitrogen atom of the thiourea group, and an alkylic chain is attached to O 7 and ends with a nitrogen atom (N18), to which another group, $\mathrm{R}^{\prime}$, is attached. Substituents R and $\mathrm{R}^{\prime}$ can be either cyclic or acyclic. The length of the chain between O 7 and N18 is not constant, as the chain may contain either two or three carbon atoms. The general atom numbering (figure 4.1) is referred to the case where the chain contains three carbon atoms (figure 4.1 left). When it contains only two carbon atoms, the number 16 is not present (figure 4.1, right.). The hydrogen atoms take the numbers of the atoms to which they are attached; for instance, H 2 is a hydrogen atom attached to the C 2 carbon atom.

R and $\mathrm{R}^{\prime}$ may have different nature and, therefore, different numbers of atoms. The atoms of R are numbered before the atoms of $\mathrm{R}^{\prime}$. The lowest atom number in 19 for all the R groups; the highest atom number (23) pertains to the pentagonal $R$. In order to ensure that the same $\mathrm{R}^{\prime}$ has the same
atom numbering in all the compounds (whichever the R ), the numbering of the atoms of $\mathrm{R}^{\prime}$ starts with the number 24 . Table 4.1 shows the numbering of the atoms of the different $R$ and $R^{\prime}$.

Three carbon atoms between O7 and N18

Two carbon atoms between O7 and N18

Figure 4.1. General structure of the sulfonylureas molecules considered in this work and atom numbering utilized for the atoms that are present in all the molecules. The sulfonylurea moiety is coloured in red.

Table 4.1. Atom numbering of the different R and $\mathrm{R}^{\prime}$ appearing in the compounds considered.

| Group | Structures of the groups with atom numbering |  |  |
| :---: | :---: | :---: | :---: |
| R |  |  |  |
|  |  |  |  |
|  |  |  |  |
| $\mathrm{R}^{\prime}$ |  |  |  |

### 4.1.2. Classification and naming of the molecules considered

The molecules considered were classified on the basis of their differences. This yields three criteria, namely, the nature of R, the nature of $\mathrm{R}^{\prime}$, and the length of the chain between O 7 and N18. The classification hierarchy is illustrated by the flow chart in figure 4.2.

Figure 4.2. Illustration of the hierarchy of the classification criteria used for the sulfonylureas molecules and letters selected to denote the characteristics for each criterion.

The compounds and their conformers are concisely denoted by acronyms, in which each of the features corresponding to the classification criteria is denoted by an upper-case letter, as shown in figure 4.2 and table 4.2. Using acronyms reflecting this classification is important because it facilitates comparisons of compounds with one or more similar characteristics.

Table 4.2. Letters used to denote the characteristics related to the classification of the compounds considered in this work.

| Characteristics | Letter | Description | Characteristics | Letter | Description |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Nature of R | A | Cyclopentane | Nature of $\mathrm{R}^{\prime}$ | G | Pyrrolidine |
|  | B | Cyclobutene |  | J | Morpholine |
|  | C | Cyclopropane |  | L | Diethylamine |
|  | D | Methane |  |  |  |
|  | E | Ethane | Length of chain between O7 and N18 | P | 3 carbons |
|  | F | Propane |  | Q | 2 carbons |

### 4.1.3. List of the molecules considered

36 compounds were considered in this work. Table 4.3 lists all the compounds, showing their structures and giving their chemical names and the acronyms used in this work to denote them concisely. The molecules are grouped into 6 groups on the basis of the nature of R (groups $\mathrm{A}, \mathrm{B}$, C, D, E and F, table 4.2).

Table 4.3. List of the compounds considered in this work. The space under each structure reports the IUPAC name of that structure, and (in a separate line) the acronym used in this work

(3)

### 4.2. Selection of the computational methods

The selection of the computational methods for this study was based on a balance between results' accuracy and affordability of the computational cost.

All the calculations were done in vacuo using two methods with different nature: Hartree-Fock (HF), an ab initio method, and the Density Functional Theory (DFT) method. All the calculations were performed with full geometry optimization to identify the closest stable conformation for
each input considered. The $6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ basis set was used for HF calculations. This level had proven to be the simplest, less expensive method capable of giving reasonable views of conformational preferences for other classes of molecules [198, 199].

The DFT calculations utilized the Becke, 3-parameter, Lee-Yang-Parr (B3LYP) functional [8487] with the $6-31+G(d, p)$ basis set. It was decided to use a basis set containing also the diffuse functions on the heavy atoms because this contributes to a better description of hydrogen bonding.

Frequency calculations were performed at both the HF/6-31G(d,p) and the DFT/B3LYP/6$31+G(d, p)$ levels. They were performed as single point calculations on the corresponding (HF and DFT) optimized geometries. The calculated frequencies were scaled by 0.8992 for HF calculations and 0.9648 for DFT calculations [200].

### 4.3. Preparation of inputs

Different inputs were prepared considering the relevant aspects by which the conformers may differ, resulting in criteria for identifying the conformers. These include considering different orientations of the thiourea group with respect to the benzene ring by rotation of the $\mathrm{C} 4-\mathrm{S} 8$ bond; different orientations of the atoms in the thiourea group by rotating single bonds; and different orientations of the chain between O 7 and N18 with respect to the benzene ring, by changing the C6-C1-O7-C15 dihedral angle. The geometry of the rest of the chain between O7 and N18 was taken as linear, as the usually preferred one.

### 4.4. Computational results

### 4.4.1. Identification and naming of conformers

The energy and the geometry of the conformers are influenced by the following factors: the presence of intramolecular hydrogen bonds (IHBs); the orientation of the chain between O 7 and N 18 with respect to the benzene ring ( $\mathrm{C} 6-\mathrm{C} 1-\mathrm{O} 7-\mathrm{C} 15$ dihedral angle); the orientation of R with respect to the sulfonylurea moiety. The orientation of the sulfonylurea moiety with respect to the
benzene ring and the geometry of the sulfonyl urea moiety itself are determined by the IHBs and, therefore, they are not considered separately.

The description of a conformer must specify all these characteristics. In order to specify them concisely, lowercase letters are utilized to denote each of them. The letters are combined into acronyms used to denote individual conformers. Letters in combination with numbers are used to denote identified different orientations of R with respect to the benzene ring, in correspondence to the different dihedral angles. All the letters and their meanings are listed in table 4.4.

Table 4.4. Characteristics of the conformers of the molecules considered and letters utilized to denote them concisely.

| Symbol | Meaning |
| :---: | :---: |
| m | Three simultaneous IHBs present (H11 $\cdots \mathrm{O} 10, \mathrm{H} 11 \cdots \mathrm{O} 13$ and H14 $\cdots \mathrm{O} 9$ ); the $\mathrm{C} 4-\mathrm{S} 8-\mathrm{N} 11-\mathrm{H} 11$ dihedral angle is $\approx 86^{\circ}$ |
| p | Three simultaneous IHBs present (H11 $\cdots \mathrm{O} 9, \mathrm{H} 11 \cdots \mathrm{O} 13, \mathrm{H} 14 \cdots \cdot \mathrm{O} 10)$; the C4-S8-N11-H11 dihedral angle is $\approx-86^{\circ}$ |
| k | Two simultaneous IHBs present (H11 $\cdots \mathrm{O} 13, \mathrm{H} 14 \cdots \mathrm{O} 10$ ); the $\mathrm{C} 4-\mathrm{S} 8-\mathrm{N} 11-\mathrm{H} 11$ dihedral angle is $\approx-55^{\circ}$ |
| g |  |
| j | The $\mathrm{C} 4-\mathrm{S} 8-\mathrm{N} 11-\mathrm{H} 11$ dihedral angle is $\approx-42^{\circ}$ |
| q | The $\mathrm{C} 6-\mathrm{C} 1-\mathrm{O} 7-\mathrm{C} 15$ dihedral angle is $\approx 180^{\circ}$ |
| r | The $\mathrm{C} 6-\mathrm{C} 1-07-\mathrm{C} 15$ dihedral angle is $\approx 0^{\circ}$ |
| s | The $\mathrm{C} 6-\mathrm{C} 1-\mathrm{O} 7-\mathrm{C} 15$ dihedral angle is $\approx 90^{\circ}$ |
| t | The $66-\mathrm{C} 1-\mathrm{O} 7-\mathrm{C} 15$ dihedral angle is $\approx-90^{\circ}$ |
| u1 | The H14-N14-C19-H19 dihedral angle is $\approx 163^{\circ}$ for A |
| u2 | The H14-N14- $12-\mathrm{H} 19$ dihedral angle is $\approx 12^{\circ}$ for A |
| u3 | The H14-N14- $\mathrm{C} 19-\mathrm{H} 19$ dihedral angle is $\approx-163^{\circ}$ for A |
| u4 | The H14-N14- $\mathrm{C} 19-\mathrm{H} 19$ dihedral angle is $\approx-12^{\circ}$ for A |
| v1 | The H14-N14- $\mathrm{C} 19-\mathrm{H} 19$ dihedral angle is $\approx 163^{\circ}$ for B |
| v2 | The H14-N14- $19-\mathrm{H} 19$ dihedral angle is $\approx 12^{\circ}$ for B |
| v3 | The H14-N14- $\mathrm{C} 19-\mathrm{H} 19$ dihedral angle is $\approx-163^{\circ}$ for B |
| v4 | The H14-N14- $\mathrm{C} 19-\mathrm{H} 19$ dihedral angle is $\approx-12^{\circ}$ for B |
| v5 | The H14-N14- C19-H19 dihedral angle is $\approx 98^{\circ}$ for B |
| w1 | The H14-N14- $\mathrm{C} 19-\mathrm{H} 19$ dihedral angle is $\approx 133^{\circ}$ for C |
| w2 | The H14-N14- $\mathrm{C} 19-\mathrm{H} 19$ dihedral angle is $\approx 19^{\circ}$ for C |
| w3 | The H14-N14- $\mathrm{C} 19-\mathrm{H} 19$ dihedral angle is $\approx-113^{\circ}$ for C |
| w4 | The H14-N14- $\mathrm{C} 19-\mathrm{H} 19$ dihedral angle is $\approx-19^{\circ}$ for C |
| w5 | The H14-N14- $19-\mathrm{H} 19$ dihedral angle is $\approx 90^{\circ}$ for C |
| w6 | The H14-N14- $\mathrm{C} 19-\mathrm{H} 19$ dihedral angle is $\approx-90^{\circ}$ for C |
| x1 | The H14-N14- $\mathrm{C} 19-\mathrm{C} 20$ dihedral angle is $\approx 40^{\circ}$ for E and F |
| x2 | The H14-N14- $\mathrm{C} 19-\mathrm{C} 20$ dihedral angle is $\approx 90^{\circ}$ for E and F |
| x3 | The H14-N14- $\mathrm{C} 19-\mathrm{C} 20$ dihedral angle is $\approx-40^{\circ}$ for E and F |

| x 4 | The H14-N14-C19-C20 dihedral angle is $\approx-90^{\circ}$ for E and F |
| :--- | :--- |

Five different types of IHBs can be present in these molecules, for a maximum of three in each conformer. These IHBs are: N11-H11 $\cdots \mathrm{O} 9, \mathrm{~N} 11-\mathrm{H} 11 \cdots \mathrm{O} 10, \mathrm{~N} 11-\mathrm{H} 11 \cdots \mathrm{O} 13, \mathrm{~N} 14-\mathrm{H} 14 \cdots$ O9 and $\mathrm{N} 14-\mathrm{H} 14 \cdots \mathrm{O} 10$. The $\mathrm{N} 11-\mathrm{H} 11 \cdots \mathrm{O} 9$ and $\mathrm{N} 11-\mathrm{H} 11 \cdots \mathrm{O} 10$ IHB cannot be present simultaneously in the same conformer; similarly, the N14-H14 $\cdots$ O 9 and N14-H14…O10 IHBs cannot be present simultaneously in the same conformer.

When three IHBs are present simultaneously in a conformer, the two following combinations are possible: N11-H11 $\cdots \mathrm{O} 9$, N11-H11 $\cdots$ O13 and N14-H14 $\cdots \mathrm{O} 10$ or N14-H14 $\cdots$ O9, N11$\mathrm{H} 11 \cdots \mathrm{O} 13$ and $\mathrm{N} 14-\mathrm{H} 14 \cdots \mathrm{O} 9$. They are denoted as m and p respectively, and they correspond to opposite orientations of the $\mathrm{C} 4-\mathrm{S} 8-\mathrm{N} 11-\mathrm{H} 11$ dihedral angle. Therefore, these conformers are symmetrical. The three simultaneous IHBs involve bifurcation on the H 11 hydrogen atom (N11$\mathrm{H} 11 \cdots \mathrm{O} 9$ and $\mathrm{N} 11-\mathrm{H} 11 \cdots \mathrm{O} 13$, or $\mathrm{N} 11-\mathrm{H} 11 \cdots \mathrm{O} 10$ and $\mathrm{N} 11-\mathrm{H} 11 \cdots \mathrm{O} 13)$. Figure 4.3 shows these two combinations. Altogether, all the five different IHBs are shown in the figure 4.3.

When two IHBs are present simultaneously in a conformer, the following options are possible: $\mathrm{N} 11-\mathrm{H} 11 \cdots \mathrm{O} 13$ and $\mathrm{N} 14-\mathrm{H} 14 \cdots \mathrm{O} 9$ or $\mathrm{N} 11-\mathrm{H} 11 \cdots \mathrm{O} 13$ and $\mathrm{N} 14-\mathrm{H} 14 \cdots \mathrm{O} 10$; there is no bifurcation. The N11-H11 $\cdots$ O13 IHB is always present when two or three IHBs are present simultaneously in a conformer. When only one IHB is present in a conformer, it is either N11$\mathrm{H} 11 \cdots \mathrm{O} 9$ or $\mathrm{N} 11-\mathrm{H} 11 \cdots \mathrm{O} 10$.

Figure 4.3. Examples of conformers containing three IHBs simultaneously.

The figure shows the two possible combinations, respectively denoted as m and p . The IHBs are indicated by dotted segments and different colours are used for each IHB: blue for H11 $\cdots$ O10, red for H14 $\cdots$ O9, green for $\mathrm{H} 11 \cdots$ O13, purple for $\mathrm{H} 14 \cdots \cdot \mathrm{O} 10$, dark orange for $\mathrm{H} 11 \cdots \mathrm{O} 9$.

Five different orientations are possible for the thiourea group with respect to the benzene ring. They differ by the value of the $\mathrm{C} 4-\mathrm{S} 8-\mathrm{N} 11-\mathrm{H} 11$ dihedral angle (table 4.3, figure 4.4).

Figure 4.4. Different orientations of the thiourea group with respect to the benzene ring and corresponding values of the $\mathrm{C} 4-\mathrm{S} 8-\mathrm{N} 11-\mathrm{H} 11$ dihedral angles. The letters denoting the given orientations in the conformers' acronyms are indicated in parentheses.

Four different orientations of the chain between O 7 and N 18 with respect to the benzene ring are possible, corresponding to four different values of the C6-C1-O7-C15 dihedral angle. The orientations are denoted by the letters $\mathrm{q}, \mathrm{r}, \mathrm{s}$ and t (table 4.3) as illustrated in figure 4.5. The orientations corresponding to the letters q and r are the most frequent.

Figure 4.5. Illustration of the different geometries of the chain between O7 and N18 with respect to the benzene ring. The value of the $\mathrm{C} 6-\mathrm{C} 1-\mathrm{O} 7-\mathrm{C} 15$ dihedral angle is shown under each image, followed by the letter denoting these features in the conformers' acronyms.

The conformational preferences of individual molecules are mostly influenced by the intramolecular hydrogen bonds (IHBs), and therefore, the characteristics of the IHBs will be given specific attention (section 4.4.3.3). On comparing different molecules, it is clear that the nature of R and $\mathrm{R}^{\prime}$ have greater influence than the length of the chain between O 7 and N18. Therefore, this influence will be analysed more in detail. Since two computational methods have been used in this study, it is also interesting to compare the trends identified by the results of the two methods.

### 4.4.2. Organization of the material presenting results

### 4.4.2.1. Organisation criteria

The data obtained for the computational results are organized in tables, and those that require images are also organized in figures. All these tables and figures are at the end of the thesis in a separate chapter (chapter 6); including them in the text would make readability difficult because they are bulky. Only tables and figures that are sufficiently small and essential for the comprehension of the text are inserted in the text. Tables presenting the ranges of each of the molecular properties considered in the analysis are included at the end of this chapter (tables 4.5-4.15).

Both in the tables and in the figures, the compounds are listed according to their groups ( $\mathrm{A}, \mathrm{B}, \mathrm{C}$, D, E and F). Within each group, the compounds are listed in alphabetical order based on the letters denoting the different $\mathrm{R}^{\prime}(\mathrm{G}, \mathrm{J}, \mathrm{L})$ and the letters denoting the different O 7 to N18 chain lengths (P and Q). For example, in group A, the compounds are listed as follows: AGP, AGQ, AJP, AJQ, ALP, ALQ. The conformers of the same compound are listed in order of increasing DFT relative energies.

### 4.4.2.2. Summary of tables in chapter 6

In all the tables reporting numerical values, both the HF and DFT results are included. The tables are grouped according to the properties considered, and, for each property, there is one table for each compound. The contents of the tables are as follows:

- Table 6.1-6.36 report the relative energies, the HOMO-LUMO energy gaps and the dipole moments of individual conformers for each of the compounds considered. These properties were grouped together in order to avoid increasing the number of separate tables for different properties, and also to be able to easily identify possible relationship or correspondences between the relative energies and the other two properties. As will be explained later, in many cases, conformers with very close, almost identical relative energies were obtained from different inputs, with both calculation methods; all these conformers were included in the tables to present all the results obtained.
- Tables 6.37-6.72 report the relative energies corrected for zero-point energy and the Gibbs free energies (sum of electronic and thermal free energies) from the frequency calculations. The uncorrected energies (from tables 6.1-6.36) are reported in the first column for comparison purposes.
- Tables 6.73-6.108 report the ZPE corrections and the corrections to the Gibbs free energies.
- Tables 6.108-6.144 report the parameters of the hydrogen bonds (bond lengths, $\mathrm{N} \cdots \mathrm{O}$ distances (donor $\cdots$ acceptor distances), and NHOO bond angles). All the IHBs present in the conformers are included. The conformers without any IHB are not included in these tables.
- Tables 6.145-6.180 report the vibrational frequencies (harmonic approximation) of the N11-H11 and N14-H14 bonds for all conformers in each of the molecules considered.
- Tables 6.181-6.216 show the red shifts (section 4.3.3.6) in the vibrational frequencies of the N11-H11 and N14-H14 bonds for all the cases in which these two bonds are engaged in an IHB.

### 4.4.2.3. Summary of figures in chapter 6

There are four sets of figures, namely:

- Figures 6.1-6.36, showing the optimized geometries of the calculated conformers of each compound
- Figures 6.37-6.72, showing the shapes of the HOMO and LUMO molecular orbitals of the calculated conformers of each compound
- Figures 6.73-6.108, showing graphs comparing the relative energies from the DFT and HF results.
- Figures 6.109-6.144, showing graphs comparing the uncorrected relative energies, the relative energy corrected for ZPE, and the Gibbs free energies from DFT and HF results.

### 4.4.2.4. Appendix A

This appendix contains tables providing information about relations between inputs and outputs, to highlight cases where different inputs optimise to the same outputs:

- Tables A1-A36 shows the input geometries and the resulting outputs conformers for all the compounds.
- Table A37-A38 shows the types of conformers and what they optimized to for different $\mathrm{R}^{\prime}$ group.

### 4.4.3. Relative energies

### 4.4.3.1. Factors influencing conformers' relative energies

### 4.4.3.1.1. Conformers differing by the intramolecular hydrogen bonds present and the related geometry of the thiourea group

The relative energies of the conformers (tables 6.1-6.36) are greatly influenced by the types and numbers of the IHBs present and by the associated geometry of the thiourea group.

For most of the molecules considered, most conformers have relative energies below $4 \mathrm{kcal} / \mathrm{mol}$ and contain IHBs. The majority of the low energy conformers have three simultaneous IHBs (m and p conformers); others have two simultaneous IHBs (k conformers); and few conformers have only one IHB (g conformers). Most of the conformers whose relative energy is not much greater than $4 \mathrm{kcal} / \mathrm{mol}$ have one IHB ( g conformers). The highest energy conformers have no IHBs ( j conformers). Conformers of different types have different relative energy ranges, depending on the compound; the ranges are shown in table 4.5 .

The lowest energy conformer of each of the molecules considered has three simultaneous IHBs, with the exception of the BLP-k-q-v1 conformer, with relative energies $0.000 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}$ and $0.132 \mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$ (table 6.11, figure 6.11), which has only two simultaneous IHBs.

Figure 4.5 shows a conformer (CJP-m-r-w1) with three simultaneous IHBs, visualized using a space filling model to better highlight the IHBs. The image shows all the IHBs possible for the m combination. The H14 $\cdots$. O9 IHB appears in the bottom part of the image. The bifurcated $\mathrm{H} 11 \cdots \mathrm{O} 10$ and $\mathrm{H} 11 \cdots \mathrm{O} 13$ IHBs are seen in the top part of the image. The two $\mathrm{sp}^{2}$ oxygen atoms O 10 and O 13 are on either side of H11and each of them forms an IHB with H11 (H11 $\cdots \mathrm{O} 10$ and $\mathrm{H} 11 \cdots \mathrm{O} 13$ respectively); in this way, H 11 is donor to both O 10 and O13. The image also shows the better directionality of the $\mathrm{H} 14 \cdots \mathrm{O} 9 \mathrm{IHB}$ and the poorer directionality of the two bifurcated

IHBs (H11 $\cdots \mathrm{O} 9$ and $\mathrm{H} 11 \cdots \mathrm{O} 13)$. The directionality of the H14 $\cdots \mathrm{O} 9$ IHB suggests that it is stronger than the bifurcated IHBs. The fact that H14 $\cdots$.O9 closes a six-member ring also suggests that it is stronger than the other two IHBs, which close four member rings. The conformer shown in fig. 4.6 is an m conformer, similar situations can be observed for the p conformers.

Figure 4.6. Space filling image of conformer CJP-m-r-w1, having three simultaneous IHBs. (Relative energy of this conformer: $0.229 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}$ and $0.664 \mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$ ).

The $m$ and $p$ conformers differ only by the combinations of three simultaneous IHBs. They are symmetrical (section 4.4.1). They mostly have the same relative energies, or their energy difference is negligible. For example, conformers AJQ-p-r-u3 and AJQ-m-q-u1 have very close relative energies $(0.615 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}, 0.707 \mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$ and $0.617 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}, 0.713$ $\mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$ respectively; table 6.4 , figure 6.4 ). When conformers differ by other factors besides the IHBs, their energies can be significantly different. For example, the relative energies ( $\mathrm{kcal} / \mathrm{mol}$ ) of CJP-p-q-w3 and CJP-m-q-w2 are 0.000/DFT, 0.000/HF and $2.830 / \mathrm{DFT}, 3.663 / \mathrm{HF}$ respectively (table 6.15); this relative energy difference may be due to the different orientations of the $\mathrm{R}=$ cyclopentyl group (as indicated by the w3 and w2 symbols).

Figure 4.7 shows space filling models of a sample k conformer (AJQ-k-q-u1). The molecule is viewed from two different perspectives to better highlight the two IHBs. The directionality of the $\mathrm{H} 14 \cdots \mathrm{O} 10 \mathrm{IHB}$ is clearly better than the directionality of the $\mathrm{H} 11 \cdots \mathrm{O} 13$.

Figure 4.7. Space filling images of conformer AJQ-k-q-u1, which has two simultaneous IHBs. (Relative energy of this conformer: $1.175 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}$ and $1.466 \mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$ ).

In most cases, the k conformers have higher relative energies than the m and p conformers, although remaining in the range of the lower energy conformers. This is because the k conformers have one IHB less than the $m$ and $p$ conformers, implying that the $m$ and $p$ conformers are more stabilized than the k conformers. Their relative energies are comparatively close; for instance, the highest energy k conformer of compound AJQ (AJQ-k-r-u1) has relative energies 1.974 $\mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}$ and $2.390 \mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$ (table 6.4) (the lowest energy k conformer of AJQ is shown in fig. 4.7).

The only case where a k conformer has the lowest relative energy concerns compound BLP, where the BLP-k-q-v1 conformer has $0.000 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}$ and $0.132 \mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$ relative energy.

There are also cases in which some k conformers have relative energies slightly lower than that of some $m$ and $p$ conformers. An example is offered by conformer ALQ-k-r-u1, with relative energies $1.365 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT} 1.661 \mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$, which is lower than that of conformer ALQ-m-r-u2, with relative energies $1.764 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}$ and $1.801 \mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$, (table 6.6.). This may be related to the fact that the $\mathrm{N} 14-\mathrm{H} 14 \cdots \mathrm{O} 9$ IHB has shorter bond length in ALQ-k-r-u1 than in ALQ-m-r-u2, suggesting that the IHB is stronger in ALQ-k-r-u1 than in ALQ-m-r-u2. More detailed analysis of the IHBs and their stabilizing effect is presented in section 4.4.3.3.

Conformers with only one IHB (g conformers) are observed only in some of the molecules. Their relative energies still remain comparatively low, mostly between $3 \mathrm{kcal} / \mathrm{mol}$ and $5 \mathrm{kcal} / \mathrm{mol}$. For example, the relative energies of FGP-g-r-x1 are $4.949 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}$ and $3.327 \mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$; the relative energies of FGQ-g-r-x1 are $4.917 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}$ and $3.371 \mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$; and the relative energies of DGP-g-r are $4.630 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}$ and $3.002 \mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$.

Conformers with no IHB ( j conformers) are the ones with the highest relative energies for all the compounds. For example, CLQ-j-r-w5 has relative energies $9.967 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}$ and 9.442 $\mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$. The space filling models in fig 4.8 illustrate the probable reasons. The model on the left indicates the presence of repulsion between the two nitrogen atoms because, with this geometry, they are very close to each other and their repulsion is not smoothed by an IHB between them. The model on the right indicates that the three oxygen atoms are also sufficiently close to each other to perceive mutual repulsion.

Figure 4.8. Space filling images of conformer CLQ-j-r-w5 - a conformer without any IHB. The two images show two different perspectives.
(Relative energy of this conformer: $9.967 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}$ and $9.442 \mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$ ).

The importance or the stabilizing effect of the IHBs is also shown by the fact that some of the inputs without IHBs optimized to conformers with one or more IHBs, yielding conformers which are mostly among those with the lowest relative energies. In this way, some low-energy conformers were obtained from more than one calculation, with different inputs, as indicated in the appendix (tables A1-A36). For example, conformer BJP-p-q-v3 was obtained from the calculations of different inputs (table A9). The fact that some conformers were obtained from different inputs supports the assumption that the conformational search that has been performed in this work is sufficiently complete to include all the low energy conformers.

### 4.4.3.1.2. Conformers differing by the orientations of the chain between 07 and N 18 with respect to the benzene ring

For most molecules, the relative energies of the individual conformers also differ by the orientation of the chain between O 7 and N 18 with respect to the benzene ring (indicated by the $\mathrm{C} 6-\mathrm{C} 1-\mathrm{O} 7-$

C15 dihedral angle). In $q$ and $r$ type conformers, the chain is on the same plane as the benzene ring, and its orientations in the two conformers are symmetrical, as shown by the values of the C6-C1-O7-C15 dihedral angle (table 4.4). When the other characteristics are the same, the q and r conformers have very close relative energies. For example, the AJQ-m-q-u2 conformer has relative energies $0.465 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}$ and $0.456 \mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$ and the AJQ-m-r-u2 conformer has relative energies $0.470 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}$ and $0.455 \mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$ (table 6.4, figure 6.4).

In s and type conformers, the chain between O 7 and N 18 is perpendicular to the plane of the benzene ring, and its orientations in the two conformers are symmetrical, as shown by the values of the C6-C1-O7-C15 dihedral angle (table 4.4). When the other characteristics are the same, the $s$ and $t$ conformers have very close relative energies. For example, the BGP-p-s-v3 conformer has relative energies $0.000 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}$ and $2.428 \mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$ and the BGP-p-t-v3 conformer has relative energies $0.000 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}, 2.454 \mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$, (table 6.7, figure 6.7 ).

Both the q and the r conformers are present in all the considered compounds, whereas the s and t conformers may be present together, or only one for a given compound, or not present at all. The s conformers are mostly observed in the compounds with three carbons between O7 and N18 (P compounds) and the $t$ conformers are mostly observed in the compounds with two carbons between O7 and N18 (Q compounds).

### 4.4.3.1.3. Influence of the nature of $\mathbf{R}^{\prime}$ on the conformational preferences of the compounds

Three different $\mathrm{R}^{\prime}$ groups may be present in the compounds considered in this work (figure 4.2): pyrrolidine, morpholine and diethylamine, respectively denoted as $\mathrm{G}, \mathrm{J}$ and L in the compounds' acronyms (table 4.1). All of them contain a nitrogen atom (N18). Twelve compounds have been considered for each $\mathrm{R}^{\prime}$ group, and this enables reliable comparisons for the identification of the influence and effect of each $\mathrm{R}^{\prime}$ group.

The same geometry of the rest of the molecule has been used for inputs with each of the three different $\mathrm{R}^{\prime}$. The outputs show that $\mathrm{R}^{\prime}$ can influence the geometry of the thiourea group even if it is comparatively far away from it; therefore, the nature of $\mathrm{R}^{\prime}$ influences the types and number of

IHBs that can be formed and because of this, some conformers are not possible for certain compounds with a given $\mathrm{R}^{\prime}$ group.

Most of the compounds with $\mathrm{R}^{\prime}=$ pyrrolidine can have all the conformer types; in few cases, some types are not possible, and inputs of that type optimized to other geometries (table A37). For the compounds with $\mathrm{R}^{\prime}=$ morpholine and $\mathrm{R}^{\prime}=$ diethylamine, the g conformers are not observed, and the g-type inputs optimized to different geometries (tables A38 and A39). This observation further highlights the influence of the $\mathrm{R}^{\prime}$ on the type of stable geometries of the given compound. It is also to be noted that the k conformers are not possible for the compounds of group C , regardless of the type of $R^{\prime}$ present, whereas the $m$ and the $j$ conformers are possible for all the compounds.

### 4.4.3.1.4. Relative energies corrected for ZPE and Gibbs free energy

The calculation of vibrational frequencies also provides the relative energies corrected for ZPE (zero point energy) and the Gibbs free energies (sum of electronic and thermal free energies). The uncorrected relative energies, the relative energy corrected for ZPE and the Gibbs free energies are compared in tables 6.37-6.72 and their trends are highlighted in the diagrams of figures 6.1096.144 .

For most compounds, the energy increasing sequence is the same or very similar for the three cases; where there are reversals between energetically neighbouring conformers, they usually involve marginal differences, mostly below $0.1 \mathrm{kcal} / \mathrm{mol}$; there are only few cases in which the difference is greater than $0.1 \mathrm{kcal} / \mathrm{mol}$, but it remains smaller than $0.5 \mathrm{kcal} / \mathrm{mol}$. These trends can be better illustrated through examples. Figures 6.122 and 6.128 , concerning compounds CGQ and DGQ respectively, are here selected as illustrative examples. The energy difference among the first four conformers of these compounds is marginal. The energy differences between neighbouring conformers with different number of IHBs show correspondence of trends for the uncorrected relative energy, the relative energy corrected for ZPE and the Gibbs free energy. For all compounds, and for all these three types of energies, the energy difference between the highest energy conformer having at least one IHBs and the lowest energy conformer without any IHB is large, confirming the dominant role of IHB on conformational preferences.

The energy differences between neighbouring conformers with different number of IHBs ( $\mathrm{m} / \mathrm{p}, \mathrm{k}$, g and j conformers) are comparable for the uncorrected relative energies, relative energies corrected ZPE and the Gibbs free energy. This is the same for all the compounds considered. It can also be noted that the energy difference between the neighbouring conformers are mostly slightly smaller for the Gibbs free energy than for the ZPE-uncorrected and corrected relative energies. This is easily observed in most of the relative energies diagrams for most of the compounds considered (figures 6.109-6.144).

The three quantities often have close values for the lower energy conformers, with no regular pattern about which is greater. For instance, for compound BKLP (figure 6.119) the values of the Gibbs free energy are greater than the other two, except for the high energy conformers (conformers without IHBs). For high energy conformers, the uncorrected relative energy is mostly greater than the corrected one, and the Gibbs free energy is smaller than the other two.

Table 6.73-6.108 report the ZPE corrections for the electronic energy and the thermal corrections for the Gibbs free energy. They are also obtained from the frequency calculations. Their ranges are reported I table 4.6, to enable a comparison of these properties within the same group of molecules and also across all the group of all the molecules considered.

The ZPE corrections are different for different molecules, but very close for the individual conformers for each of the molecules considered. The values of the ZPE corrections are always greater than the values of the thermal corrections for the Gibbs free energy for each of the molecules considered. The corrections are greater for the conformers of the compounds of group A. The ZPE corrections of the individual conformers of the same compound differ by less than 3 $\mathrm{kcal} / \mathrm{mol}$ for all the compounds considered, and the thermal corrections to the Gibbs free energy of the individual conformers differ by less than $5 \mathrm{kcal} / \mathrm{mol}$.

### 4.4.3.2 Comparison of conformational preferences and energetics in the HF and DFT results

The comparison of the results obtained with the two methods follows a similar pattern (in terms of analysis terms) as the analysis in the previous section. Furthermore, these comparisons mostly utilise tables and diagrams already mentioned in the previous analysis, because they report both the DFT and the HF results.

### 4.4.3.2.1 Comparisons of the relative energies

For most of the molecules considered, the conformer with the lowest relative energy is the same for both DFT and HF (with the same or similar geometry in the two cases). An example is offered by the ALQ-m-r-u1 conformer (table 6.6, figure 6.6).

In other cases, the conformers with the lowest relative energies are different for the two methods. For example, for compound BLP, the conformer of with the lowest relative energy is BLP-k-q-v1 for DFT and BLP-m-r-v1 for HF.

For the other conformers besides for the lowest energy one, the conformers' relative energy sequence is the same in the HF and DFT results for most compounds, but there are reversals for some conformers. When the values of the relative energies are different, but very close, the geometries of the concerned conformers are identical. In most cases, the difference in the relative energies of the lower energy conformers is very small for both methods.

### 4.4.3.2.2. Comparison of the influence of the orientation of the chain between $O 7$ and $N 18$ with respect to the benzene ring

As already mentioned, (section 4.3.2.1.1), the pairs of $\mathrm{q} / \mathrm{r}$ and $\mathrm{s} / \mathrm{t}$ conformers of the same compound have the same or very close relative energies with both the methods. This is because the two conformers of a pair are symmetrical, and all their features are the same except for the different orientation of the chain - parallel to the plane of the benzene ring ( $\mathrm{q} / \mathrm{r}$ ) or perpendicular to it $(\mathrm{s} / \mathrm{t})$. Conformers not belonging to the same $\mathrm{q} / \mathrm{r}$ or s/t pairs may have different relative energies with the two methods. This may happen for $q$ and $t, q$ and $s, r$ and $t$ or $r$ and $s$ conformers. For example, the BLP-k-r-v1 and the BLP-k-s-v1 conformers have the same relative energies with DFT (0.219 $\mathrm{kcal} / \mathrm{mol})$, but different relative energies with $\mathrm{HF}(0.377 \mathrm{kcal} / \mathrm{mol}$ and $2.755 \mathrm{kcal} / \mathrm{mol}$ respectively; table 6.11, figure 6.11) The two conformers are both k conformers with the same geometry of the R group, which may account for the similarity in their DFT relative energies, although in one of them the chain between O 7 and N 18 is perpendicular to the plane of the benzene ring and in the other is parallel, which may account for the different HF relative energies.

It also happens that s conformers may have the same DFT relative energies as either the r or the q conformers of the same compound, but very different HF relative energies. For example, the BJQ-p-r-v3 conformer has relative energies $2.133 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}, 2.171 \mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$ and the BJQ-p-sv3 conformer has relative energies $2.133 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}, 4.589 \mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$ (table 6.10 , figure 6.10). In BJQ-p-r-v3, the orientation of the chain between O7 and N18 is parallel to the plane of the benzene ring, and in BJQ-p-s-v3 conformer it is perpendicular. These cases suggest that the HF calculation method gives more importance to the orientation of the chain between O7 and N18 than DFT.

It happened that different inputs resulted in conformers with the same HF relative energies, but different DFT results. These conformers have symmetrical geometries. For example, BLP-p-q-v4 has relative energies $1.679 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}, 1.419 \mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$ and BLP-p-r-v4 has relative energies $1.708 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}, 1.419 \mathrm{kcal} / \mathrm{mol} \mathrm{HF}$, (table 6.11 and figure 6.11 , table A11); the two conformers have symmetrical geometries.

There are also conformers with different geometries but very close or the same relative energies. For example, AGP-m-q-u1 has relative energies $0.036 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}, 0.031 \mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$ and AGP-p-r-u3 $0.037 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}, 0.030 \mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$ (table 6.1 , figure 6.1 ). This may be due to the fact that, in both conformers, the orientation of the chain between O 7 and N 18 is parallel to the plane of the benzene ring, and to the fact that geometry difference in the R group do not have much influence on the relative energies of the conformers.

There are also several cases where conformers with different geometries have the same or very close DFT relative energy. For example, AJQ-p-q-u3 has relative energy $0.583 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}$, $0.000 \mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$ and AJQ-m-r-u 1 r has relative energy $0.583 \mathrm{kcal} / \mathrm{mol} / \mathrm{DFT}, 0.689 \mathrm{kcal} / \mathrm{mol} / \mathrm{HF}$ (table 6.4, figure 6.4). The orientation of the chain between O7 and N18 is parallel to the plane of the benzene ring in both conformers. The difference in the geometry of the R group may be responsible for the difference in the HF relative energies of the two conformers.

### 4.4.3.2.3. Comparison of the influence of the nature of the $R^{\prime}$ group

For most of the considered compounds (and for all the G, J and L compounds), the conformers with the lowest relative energy are the $\mathrm{m} / \mathrm{p}$ conformers, with both DFT and HF methods. The only
exception is BLP, whose lowest energy conformer is a k conformer for DFT and an $\mathrm{m} / \mathrm{p}$ conformer for HF. For all these compounds, the relative energies of individual conformers having IHBs are mostly below $3 \mathrm{kcal} / \mathrm{mol}$ in the DFT results; however, for the G compounds, the g conformers may have DFT relative energies around 4 or $5 \mathrm{kcal} / \mathrm{mol}$.

The corresponding HF relative energies of individual conformers are mostly close to the DFT ones. However, some s and t conformers have higher HF relative energies in all the compounds, and the difference can reach 3 or $4 \mathrm{kcal} / \mathrm{mol}$ with respect to the DFT results.

### 4.4.3.2.4. Comparisons of uncorrected relative energies, relative energy corrected for ZPE and Gibbs free energy.

Tables 6.37-6.72 report both the DFT and the HF results for the uncorrected relative energies, relative energies corrected for ZPE and Gibbs free energies (corrected for the sum of the electronic and thermal free energies) of the individual conformers for each of the molecules considered. Figures 6.109-6.144 report diagrams comparing the trends of these three quantities (uncorrected relative energies, relative energy corrected for ZPE and the Gibbs free energy). To facilitate the comparisons, the diagrams of the DFT and HF results for the same compound are reported in the same page (one page for each compound). The energy ranges are reported in table 4.5.

The comparison of the uncorrected relative energies, relative energy corrected for ZPE and Gibbs free energy, show that, in most cases, the conformer with the lowest energy is the same with both DFT and HF. The comparative diagrams show similar trends for the DFT and HF results in a number of cases. However, in other cases the low energy conformers have very close energy values in the DFT results, but not in the HF results; furthermore, it may happen that the three types of energy have very similar trends in the DFT results, but not in the HF results. For example, for compound CGP (figure 6.121), the DFT results show very close values for the first six conformers and similar trends for the three quantities, whereas this is not true for the HF results.

The comparative diagrams also show that the energy trends are more similar for the compounds with two carbon atoms in the chain between O7 and N18 (Q compounds), than for the compounds
with three carbon atoms in the chain between O7 and N18 (P compounds) for both the DFT and HF results. This observation is true whether the DFT and HF results are similar or not, as highlighted, for example, by Figure 6.145 (compound FLP), where the trends of HF and DFT are identical, and figure 6.146 (compound FLQ) where there are some differences in the DFT and HF results.

Tables 6.73-6.108 reports the ZPE corrections for the electronic energy and the thermal corrections for the Gibbs free energy. The values of corrections for the individual conformers of the considered compounds are greater in the HF results than the DFT results.

### 4.4.3.3. Characteristics of the intramolecular hydrogen bonds

The IHBs have the strongest influence on the geometry preferences and the relative energies of the conformers and, therefore, they are given specific attention in this section. As already described in section 4.4.1., the IHBs that may be present in the calculated molecules are $\mathrm{H} 14 \cdots \mathrm{O} 9$ or H14…O10 (not present simultaneously), and H11…O13, which may be present simultaneously with either $\mathrm{H} 11 \cdots \mathrm{O} 9$ or $\mathrm{H} 11 \cdots \mathrm{O} 10$; in the latter case, the two IHBs are bifurcated on H11. When a conformer contains three simultaneous IHBs, it contains H14 $\cdots$ O 9 or H14 $\cdots \mathrm{O} 10, \mathrm{H} 11 \cdots \mathrm{O} 13$, and $\mathrm{H} 11 \cdots \mathrm{O} 9$ or $\mathrm{H} 11 \cdots \mathrm{O} 10$.

IHBs are described through their parameters: bond length, donor-acceptor distance, and bond angle. The parameters of the IHBs in the conformers of the calculated molecules are reported in tables 108-144. Their ranges are summarized in tables 4.7-4.11, devoting one table to each IHB, and the values are analysed in terms of the different compounds; since, for the two IHBs with H11 as donor, it is important to know whether there is bifurcation or not, the symbol $\alpha$ is used for the bifurcated cases and the symbol $\beta$ to specify that there is no bifurcation.

When comparing IHBs, we consider that, generally, shorter bond length corresponds to greater strength. Comparisons of the parameters of the IHBs present in the calculated molecules shows that $\mathrm{H} 14 \cdots \mathrm{O} 9$ and $\mathrm{H} 14 \cdots \mathrm{O} 10$ have the shortest bond length and, therefore, they are the strongest IHBs. This is related to the fact that the acceptor is an $\mathrm{sp}^{2} \mathrm{O}$ atom ( O 9 or O 10 ), and also to the fact that they close a six membered ring, which is a favourable ring-geometry. Although they are the
strongest in these molecules, $\mathrm{H} 14 \cdots \mathrm{O} 9$ and $\mathrm{H} 14 \cdots \mathrm{O} 10$ cannot be considered strong IHBs, because their directionality (NHO bond angle) deviates considerably from linearity. H14 $\cdots$ O9 and $\mathrm{H} 14 \cdots \mathrm{O} 10$ are present in symmetrical conformers of the same molecule: $\mathrm{H} 14 \cdots \mathrm{O} 9$ is present in m conformers and H14 $\cdots$ O10 in p conformers. H14 $\cdots \mathrm{O} 9$ is only present in m-type conformers, which are conformers with three IHBs present in all the molecules considered. It is stronger in the compounds of group C; for instance, its length-ranges for compounds CLQ are 2.058-2.065/HF and 2.025-2.034/DFT (table 4.6).

As for the IHBs for which H 11 is the donor, $\mathrm{H} 11 \cdots \mathrm{O} 13$ has shorter bond lengths than either $\mathrm{H} 11 \cdots \mathrm{O} 9$ or $\mathrm{H} 11 \cdots \mathrm{O} 10$. All three of them (H11 $\cdots \mathrm{O} 9, \mathrm{H} 11 \cdots \mathrm{O} 10$ and $\mathrm{H} 11 \cdots \mathrm{O} 13$ ) are weak IHBs. Their situation seems analogous to that of the IHB between the OH and the $\mathrm{sp}^{2} \mathrm{O}$ in the carboxylic group $(\mathrm{COOH})$ : an IHB that closes a four membered ring with a very small bond angle (section 2.3.4). It may even be questioned whether they can be truly considered IHBs, because of the bond angle. They are considered IHBs here because the conformers' energy values show that they have a stabilising effect.

When three IHBs are present (i.e., when there is bifurcation on H11, like in the m conformers), the bond lengths of all the IHBs are longer than when only two IHBs are present, like in the k and the p conformers; this suggests that the bifurcation on H11 decreases the strength of the IHBs. For example, the length ranges (table 4.7) of the H14…O10 IHB in compound ELP are 1.974-1.977 $\AA$ A DFT and 2.028-2.033 $\AA / \mathrm{HF}$ in conformers with two IHBs (no bifurcation) and 2.084$2.091 \AA / \mathrm{HF}$ and $2.054-2.055 \AA / \mathrm{DFT}$ in conformers with three IHBs (where there is bifurcation on H11); thus, it appears that the presence of bifurcation on H11 influences not only the two bifurcated IHBs, but also the other IHB present.

The H11 $\cdots$ O 9 IHB is present either simultaneously with H11 $\cdots$ O13 (p-type conformers) or in conformers in which it is the only IHB present (g-type conformers). The ranges of its length are similar for molecules pertaining to the same group (same R), but slightly different for molecules of different groups. The length is also different in different conformer-types (p or g). For example, its bond lengths are $2.446 \AA / \mathrm{DFT}, 2.396 \AA / \mathrm{HF}$ for EGP-g-r-x1 and $2.595 \AA / \mathrm{DFT}, 2.505 \AA / \mathrm{HF}$ for EGP-p-q-x3.

The H11 $\cdots$ O10 IHB is present only simultaneously with H11 $\cdots$ O13 (m-type conformers), never alone. The ranges of its length are similar for molecules of the same group and slightly different in molecules of different groups. For example, the ranges of its bond lengths (table 4.10) in the compound AGP, AGQ and ALP are 2.590-2.598/DFT and 2.499-2.512/HF.

The H11 $\cdots$ O13 IHB is present in the $\mathrm{m}, \mathrm{p}$ and k conformers; it is never present alone in a conformer, but only simultaneously to at least another IHB. Its bond length differs in conformers of different types. For example, in the ALQ compound, its bond length is 2.386-2.390/ DFT and 2.354-2.364/HF for m-type or p-type conformers (where there is bifurcation on H11), and 2.3472.348/DFT and 2.313-2.314/HF in k-type conformers, where the other IHB present is H14 $\cdots \mathrm{O} 10$.

For each of the groups of molecules considered, the parameters of each of the IHB present are very close in conformers of the same type, in the results of the same method. Comparison of the results from HF and DFT shows that, in most cases, the bond length in the DFT results is shorter than in the HF results. For instance, in the case of k conformers, the length of the H14...O9 IHB is mostly below $2.0 \AA$ in the DFT results, and longer in the HF results. This is consistent with the known tendency of HF to underestimate the strength of hydrogen bonds and of DFT to overestimate it. However, there are cases where the bond lengths are longer in the DFT results than in the HF results; this is notable in cases where there is bifurcation.

Furthermore, the similarities of the parameters of the IHBs in a given set of molecules may differ in the results of the two methods. For instance, the $\mathrm{N} \cdots \mathrm{O}$ distances for the H11‥O13 IHB are the same $(2.280 \AA$ ) in the DFT results for the molecules of group D, whereas they are different in the HF results.

The parameters of hydrogen bonds are related to their strength. It is not easy to determine the energy of individual IHBs, because their removal would substantially change the geometry of the molecule. An idea of the stabilising effect of the IHBs could be given by the difference between the energy of the lowest energy conformer without any IHB and the energy of the highest energy conformer with at least one IHB (table 4.12). These differences are different for different types of compounds. The greatest differences are observed for the JP compounds ( $\mathrm{R}^{\prime}=$ morpholine, two carbons in the chain between O 7 and N 18 ) and the smallest for G compounds ( $\mathrm{R}^{\prime}=$ pyrrolidine). This shows that the length of the chain between O7 and N18has some influence on the relative
energies of the conformers and on the stabilizing effects of the IHBs present in a conformer. The differences are very close for most of the L compounds ( $\mathrm{R}^{\prime}=$ diethylamine ).

### 4.4.3.4. Influence of the nature of $R$

Investigating possible influences by the nature of R entails comparisons of molecules with different R and the same $\mathrm{R}^{\prime}$. Therefore, the comparisons in this section will be grouped according to the types of $\mathrm{R}^{\prime}$; for each $\mathrm{R}^{\prime}$, the compounds will be sub-grouped according to the length of the chain between O7 and N18 and also to similarities in some observations made.

### 4.4.3.4.1. Comparisons of compounds with different $R$ and $R^{\prime}=$ pyrrolidine ( $G$ compounds)

The G type compounds with the chain between O7 and N18 containing three carbons (GP compounds) are AGP, BGP, CGP, DGP, EGP and FGP. The G type compounds with the chain between O7 and N18 are AGQ, BGQ, CGQ, DGQ, EGQ and FGQ. The analysis of the results confirms that the type of lowest energy conformer does not depend on R , as the conformers with the lowest relative energies are $\mathrm{m} / \mathrm{p}$ conformers for all the compounds.

The nature of R may influence the types of conformers that are possible. For example, g conformers are observed only in G compounds, but not in all of them (they are not observed for compounds BGQ and CGQ). Compounds with $\mathrm{R}=$ cyclopropane do not have the k conformers.

### 4.4.3.4.2. Comparisons of compounds with different $R$ and $R^{\prime}=$ morpholine or $R^{\prime}=$ diethylamine

The J type compounds (compounds with $\mathrm{R}^{\prime}=$ morpholine) comprise JP compounds (AJP, BJP, CJP, DJP, EJP, FJP, with of the chain between O7 and N18 containing three carbons), and JQ compounds (AJQ, BJQ, CJQ, DJQ, EJQ and FJQ, with the chain between O7 and N18 containing two carbons). The $\mathrm{L}\left(\mathrm{R}^{\prime}=\right.$ diethylamine) type compounds comprise LP compounds (ALP, BLP, CLP, DLP, ELP and FLP, with the chain between O7 and N18 containing three carbons) and LQ
compounds (ALQ, BLQ, CLQ, DLQ, ELQ and FLQ with the chain between O7 and N18 containing two carbons).

These two classes of compounds ( J and L ) are considered together in this part because of their similarities. Their relative energies show similar trends; there is not much influence of the nature of R on the type of lowest energy conformer (which is an $\mathrm{m} / \mathrm{p}$ conformer, with the exception of compound BLP, whose lowest energy conformer is a k conformer). Most of the other conformers of these compounds are also $\mathrm{m} / \mathrm{p}$ conformers; some compounds do not have k conformers. This shows that there is not much influence of the nature of R on the conformational preferences of the compounds of these two groups. The parameters of the IHBs are also very similar for these compounds.

### 4.4.3.5. IR Vibrational frequencies

The IR vibrational frequencies (harmonic approximation, section 2.4) were calculated for all the conformers of all the considered compounds. The analysis is particularly interesting for the bonds that can make IHBs, i.e., the N11-H11 and N14-H14 bonds. Their IR vibrational frequencies are reported in tables 6.180-6.216. The changes in their IR vibrational frequencies when they form IHBs are analysed in detail in section 4.3.3.6.

The vibrational frequencies of the N11-H11 bond are always greater when it forms IHBs than when it does not form any, and they are related to the types of IHBs it forms and to the presence or absence of IHB formed by $\mathrm{N} 14-\mathrm{H} 14$. The frequency is highest when it forms $\mathrm{H} 11 \cdots \mathrm{O} 9$ without bifurcation, and without the presence of IHBs formed by $\mathrm{N} 14-\mathrm{H} 14$; it is lowest when it forms $\mathrm{H} 11 \cdots \mathrm{O} 13$ without bifurcation and with the presence of $\mathrm{H} 14 \cdots \mathrm{O} 10$; it is intermediate in either of the two bifurcated cases, whether the IHB formed by $\mathrm{N} 14-\mathrm{H} 14$ is $\mathrm{H} 14 \cdots \mathrm{O} 9$ or $\mathrm{H} 14 \cdots \mathrm{O} 10$.

The vibrational frequencies of the $\mathrm{N} 14-\mathrm{H} 14$ bond are very close whether it forms $\mathrm{H} 14 \cdots \mathrm{O} 9$ (mtype conformers) or H14…O10 (p-type and k-type conformers); in the latter case, the frequency is slightly greater in the k conformers than in the p conformers.

The vibrational frequencies of the N11-H11 and N14-H14 bonds are very similar when neither of them is engaged in an IHB ( j conformers).

The two bonds often have coupled vibrations when N11-H11 forms the H11 $\cdots$ O9 IHB and N14H14 is not engaged in IHBs ( g conformers). In these cases, both the symmetric and asymmetric vibrations appear with the same frequency values for the two bonds; they are reported together for the two bonds in tables 6.145-6.180

The vibrational frequencies of $\mathrm{N} 11-\mathrm{H} 11$ and $\mathrm{N} 14-\mathrm{H} 14$ are comparatively close in the HF and DFT results, and the main differences may be related to the presence and the type of IHBs. The differences are also related to how HF and DFT estimate the strength of hydrogen bonds, and therefore they will be analysed in section 4.3.3.6.

### 4.4.3.6. Changes in the IR vibrational frequencies of the $\mathrm{N} 11-\mathrm{H} 11$ and $\mathrm{N} 14-\mathrm{H} 14$ bonds when they form IHBs

Tables 6.181-6.216 report the changes in the IR vibrational frequencies of the N11-H11 and N14H14 bonds when they form IHBs, and table 6.217 reports their ranges. The changes are taken as the difference between the average vibrational frequency of the given $\mathrm{N}-\mathrm{H}$ bond over the conformers where it does not form IHBs and its vibrational frequency in the considered conformer where it forms an IHB. In this way, a positive change indicates a decrease in the vibrational frequency and a negative change indicates an increase.

In most cases, the formation of a hydrogen bond causes a red shift in the vibrational frequency of the donor (section 2.3.5), i.e., the frequency decreases. This is also observed for N14-H14 when it is engaged in IHBs. However, the frequency of N11-H11 increases when it forms IHBs. The phenomenon is called blue shift [201-207]. The literature [206-207] reports a blue shift in the frequency of the amino $\mathrm{N}-\mathrm{H}$ bond when it is involved in bifurcated hydrogen bonds, which is comparable to the case of $\mathrm{N} 11-\mathrm{H} 11$ in the compounds considered in this work. A blue shift is accompanied by a contraction of the donor $\mathrm{X}-\mathrm{H}$ bond length in the $\mathrm{X}-\mathrm{H} \cdots \cdot \mathrm{Y}$ system. Both red shifts and blue shifts can be related to the strength of the hydrogen bond [203]. For this reason, it is also interesting to compare the magnitude of the red shifts or the blue shifts with the IHB bond lengths, to have a better idea of the relative strengths of the various IHBs.

From the tables, it is clear that the blue shift is smallest (close to negligible) when N11-H11 forms the $\mathrm{H} 11 \cdots \mathrm{O} 13 \mathrm{IHB}$ and $\mathrm{H} 14 \cdots \mathrm{O} 10$ is also present (k conformers); it is greatest when $\mathrm{N} 11-\mathrm{H} 11$
forms the H11 $\cdots$ O9 IHB and no other IHB is present ( g conformers); and intermediate in all the cases where N11-H11 forms bifurcated IHBs whether H11 $\cdots$.O13 plus H11 $\cdots$.O9 or H11 $\cdots$.O13 plus H11 $\cdots$ O10, and whichever IHB is formed by $\mathrm{N} 14-\mathrm{H} 14$ ( $\mathrm{m} / \mathrm{p}$ conformers). In this way, the blue shift is greatest when $\mathrm{H} 11 \cdots \mathrm{O} 9$ is not bifurcated and smallest when $\mathrm{H} 11 \cdots \mathrm{O} 13$ is not bifurcated; it is intermediate when there is bifurcation on H11. The IHB bond lengths suggest that either $\mathrm{H} 11 \cdots \mathrm{O} 9$ or $\mathrm{H} 11 \cdots \mathrm{O} 13$ are stronger when they are not bifurcated (with $\mathrm{H} 11 \cdots \mathrm{O} 13$ always being slightly stronger than $\mathrm{H} 11 \cdots \cdot \mathrm{O} 9$, whether alone or bifurcated).

The red shifts for the vibration of the $\mathrm{N} 14-\mathrm{H} 14$ bond are all comparable, but slightly greater when N14-H14 forms the H14 $\cdots \mathrm{O} 10 \mathrm{IHB}$ and $\mathrm{N} 11-\mathrm{H} 11$ simultaneously forms $\mathrm{H} 11 \cdots \mathrm{O} 13$ (k conformers). The bond lengths of $\mathrm{H} 14 \cdots \mathrm{O} 9$ and $\mathrm{H} 14 \cdots \mathrm{O} 10$ are very similar when the IHBs bifurcated on H 11 are also present, and so are their red shifts. However, the bond length of $\mathrm{H} 14 \cdots \mathrm{O} 10$ suggests that it is stronger when the IHBs bifurcated on H11 are not present, as indicated also by the greater red shift.

DFT and HF results show comparable trends for both blue shifts and red shifts for all the conformers except the k conformers. The increase for the blue shift or decrease for the red shift is much smaller in the HF results than in the DFT results because HF underestimates the strength of the hydrogen bonds while DFT/B3LYP overestimates it. In the case of $k$ conformers, the DFT results show a small blue shift for N11-H11, whereas the HF results show a small red shift; however, the small values of these changes could be comparable to the overestimation or the underestimation of the strength of the hydrogen bonds by the two methods, with respect to the actual strength. Furthermore, there are cases in which N14-H14 shows red shift with the DFT results and blue shift in the HF results. For example, in compound AJP (table 6.183), there is a red shift with the DFT results and blue shifts with the HF results for conformers AJP-m-r-u2, AJP-m-$\mathrm{s}-\mathrm{u} 2$ and AJP-m-q-u2.

### 4.4.3.7. Dipole moments

The dipole moments of all the conformers of all the studied molecules are included in tables 6.16.36. Their ranges can be analysed in terms of the different compounds (table 4.13), in terms of
compounds and conformers (table 4.14), or in terms of conformer types across compounds (table 4.15).

For each compound, the dipole moments can vary significantly across conformers. The ranges of the dipole moment depend on the substituents and the type of IHBs present. The difference for different compounds is largely related to the number and type of polar bonds that are present. This also means that it is related mostly to the nature of $\mathrm{R}^{\prime}$ because that is the part that can differ by the type and number of polar bonds. For example, $\mathrm{R}^{\prime}=$ morpholine ( J compounds) contains two electronegative atoms (oxygen and nitrogen), $\mathrm{R}^{\prime}=$ pyrrolidine ( G Compounds) and $\mathrm{R}^{\prime}=$ diethylamine (L compounds) contain one nitrogen atom. As a result, the dipole moments are lower in the J compounds than in the G and L compounds. For example, across the compounds of group B, the dipole moments ranges (Debye, DFT results) are 4.5103-8.2516 for BJP, 5.2828-9.9492 for BGP, 6.0489-9.7683 for BLP (table 4.12).

The dipole moments of the m and the p conformers (tables 4.14 and 4.15) are very close in most of the molecules in which they are both present. For example, in compound BGP, the ranges of the dipole moments are 6.3073-7.1291 Debye/DFT, 5.7919-6.9927 Debye/HF for m-type conformers and 6.2528-6.2533 Debye/DFT, 5.4640-5.8287 Debye/HF for the p-type conformers. This is related to the fact that the two conformer types are symmetrical and other geometrical differences do not have great effect on their dipole moments. The dipole moments of k conformers are very close to those of the $\mathrm{m} / \mathrm{p}$ conformers. For example, in the same compound BGP, the ranges of the dipole moments of the k conformers are 6.2109-6.9481 Debye/DFT, 5.7070-6.8235 Debye/HF, which are close to those of the $m$ and $p$ conformers.

The dipole moments are highest for j conformers, that is, the conformers without any IHB. This highlights the influence of IHBs on the dipole moments, which somehow may partially compensate for the effects of the polarity on the donor. The lowest dipole moments pertain to the g conformers in G compounds ( $\mathrm{R}^{\prime}=$ pyrrolidine ).

The dipole moments are comparable in both the DFT and HF results, both in terms of compound types and of conformer types.

### 4.4.3.8. The HOMO-LUMO energy gaps

The HOMO-LUMO energy gaps for the considered compounds are also included in tables 6.16.36; the ranges of their values and the range-widths for each compound are reported in table 4.16. On analysing and comparing their values, it has to be taken into account that the DFT values are much smaller than the HF values, as a well-known phenomenon of the two methods; this is the reason for comparing the ranges-width. The overall ranges, considering the smallest value and the highest value of these energy gaps across all the compounds are $115.233-122.563 \mathrm{kcal} / \mathrm{mol}$ (compounds DLQ and BJQ respectively) in the DFT results and $272.301-286.263 \mathrm{kcal} / \mathrm{mol}$ (compounds BLQ and AGQ respectively) in the HF results. The width of the ranges for most of the molecules are below $8 \mathrm{kcal} / \mathrm{mol}$; some exceptions in which the ranges are above $9 \mathrm{kcal} / \mathrm{mol}$ concern some of the $\mathrm{J}\left(\mathrm{R}^{\prime}=\right.$ morpholine $)$ and L compounds $\left(\mathrm{R}^{\prime}=\right.$ diethylamine $)$.

The comparison of the ranges of the P (compounds with 3 carbons in the chain between O 7 and N18) and Q compound (compounds with 2 carbons in the chain between O7 and N18) having the same R and $\mathrm{R}^{\prime}$ helps highlight possible dependence on R and $\mathrm{R}^{\prime}$. In the DFT results, the difference in the ranges for P and Q compounds is not large for G compounds ( $\mathrm{R}^{\prime}=$ pyrrolidine). Similarly, there is not much difference for the L compounds, except for $\mathrm{B}(\mathrm{R}=$ cyclobutyl) and $\mathrm{D}(\mathrm{R}=$ methyl) compounds. There is considerable difference for the J compounds, except for F compounds ( $\mathrm{R}=$ propyl). For Q compounds, the gap is greatest for all the J compounds and for some of the L compounds (BLQ and DLQ).

The width of the ranges of the HOMO-LUMO energy gaps are comparable for the DFT and the HF results for all the compounds except for the J compounds, for which there is a big difference between P and Q in the HF results.

The calculation outputs also enable the visualization of the shapes of the HOMO and LUMO molecular orbitals, showing the distribution of the electron density for each orbital in the different parts of the molecule. Thus, it can be seen whether the distribution of the electron density is preferably on the benzene ring, on the thiourea moiety, or on the R and $\mathrm{R}^{\prime}$ of each molecule.

The shapes of representative HOMOs and LUMOs, with different distributions within the molecules, are shown in figures 4.9 and 4.10 respectively. The distribution of the electron density does not depend significantly on R and $\mathrm{R}^{\prime}$. For the HOMO, the distribution of the electron density
depends mostly on the type of conformers and only slightly on the nature of R. For the majority of conformers across compounds, the distribution of the HOMO is similar to that of the CJP-p-s-w5 conformer (figure 4.9), that is, it is mostly on the benzene ring and also on the electronegative atoms of the thiourea group. For some conformers, the HOMO is distributed mostly on the benzene ring and the $\mathrm{R}^{\prime}$ group, similar to the CGP-p-q-w5 example (figure 4.9). There are also conformers in which the HOMO is distributed only on the $\mathrm{R}^{\prime}$ group, as in the DGP-k-s example (figure 4.9), or mostly on the benzene ring, but also on the thiourea group, and on some atoms on the $\mathrm{R}^{\prime}$ group, as in the DGQ-j-t example (figure 4.9). The distribution of the LUMO is similar in all the conformers across compounds, prevalently on the benzene ring and on the thiourea moiety.

Figure 4.9. Representative shapes of HOMOs of sulfonylureas.

Figure 4.10. Representative shapes of LUMOs of sulfonylureas.

Table 4.5. Ranges of relative energies not corrected for ZPE ( $\Delta \mathrm{E}$ ), relative energies corrected for ZPE ( $\Delta \mathrm{E}_{\text {corr }}$ ), and Gibbs free energy corrected for the sum of electronic and thermal free energies ( $\Delta \mathrm{G}_{\text {corr }}$ ) of each conformer type for each of the compounds considered.

| Mole cules | Conformer type | $\Delta \mathrm{E}(\mathrm{kcal} / \mathrm{mol})$ |  | $\Delta \mathrm{E}_{\text {corr }}(\mathrm{kcal} / \mathrm{mol})$ |  | $\Delta \mathrm{G}_{\text {corr }}(\mathrm{kcal} / \mathrm{mol})$ |  |

Table 4.7. Ranges of the parameters of the N14-H14…O10 IHB for all the compounds in which it is present.

The symbols $\alpha$ and $\beta$ are used to indicate the presence of bifurcation.

| Molecule | Bond length ranges ( $\AA$ ) |  | N $\cdots \cdot \mathrm{O}$ distance range ( $\AA$ ) |  | NĤO bond angle ranges ( ${ }^{\circ}$ ) |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | DFT | HF | DFT | HF | DFT | HF |
| AGP $\alpha$ | 2.054-2.056 | 2.086-2.088 | 2.866-2.869 | 2.858-2.861 | 135.34-135.44 | 132.92-132.94 |

## Chapter 5

## Discussion and conclusions

This chapter presents the discussion and the conclusions based on all the observations noted during the analysis of the results, as reported in chapter 4, and considerations for future studies on the molecules considered.

### 5.1. Overall discussions and inferences

The computational studies of the sulfonylureas molecules reported in this work have all been done in vacuo. Only new sulfonylureas, which are yet to be synthesized, were studied. The objective was to provide information about these compounds, which could be relevant to researchers working on them experimentally. Different R and $\mathrm{R}^{\prime}$ were considered, so that this study covers a broad variety of sulfonylureas molecules with groups that can be of interest in view of medically related properties.

Both DFT and HF methods were used in this study because of the advantages of obtaining results from two different methods. The HF/6-31G(d,p) is the cheapest option that can give reasonable results; it was considered interesting to evaluate its performance for these molecules in view of the possibility that it can be used for fast screening of a large number of molecules. The DFT/B3LYP results were used as reference in organizing the materials considered in the analysis; it appears reasonable to consider the DFT results as benchmarks because DFT takes into account also part of the electron correlation.

The most stable conformers of each of the compounds considered were successfully identified. The results show how different factors can influence the molecular properties. They show the importance of the intramolecular hydrogen bonds (IHBs) as a stabilizing factor influencing the energy of the conformers. The presence, the number, and the type of IHBs all have significant influence on the relative energy of individual conformers. The greater the number of IHBs, the lower the relative energies of the conformers. The importance of the IHBs is also made evident by the fact that the highest energy conformers are characterized by the absence of IHBs, and the
energy difference between the highest energy conformer with at least one IHB and the lowest energy conformer without any IHBs is at least $5 \mathrm{kcal} / \mathrm{mol}$ (often greater).

Five different conformer types were identified across all the compounds considered and were denoted by $\mathrm{m} / \mathrm{p}, \mathrm{k}$, g and j . They differ by the number and type of IHBs present and by some relevant geometrical features. The different conformer types have different relative energy ranges across conformers. The number of individual conformers and the conformer types differ for different compounds.

The m/p conformers (conformers with three IHBs) are the conformers with the lowest relative energies in most of the compounds considered. The k conformers (conformers with two IHBs) are also amongst the lowest energy conformers and they are also the ones with shortest IHBs, both for the H14 $\cdots \mathrm{O} 10$ and the $\mathrm{H} 11 \cdots \mathrm{O} 13$ IHBs. The g conformers (with only the $\mathrm{H} 11 \cdots \mathrm{O} 9 \mathrm{IHB}$ ) were found to have higher relative energy than the $\mathrm{m} / \mathrm{p}$ and k conformers. The j conformers (conformers without IHBs ) are always the conformers with the highest relative energies in all the compounds.

Given their importance in stabilizing the molecules, the IHBs were given specific attention. The $\mathrm{m} / \mathrm{p}$ conformers differ from the other conformer types because of the presence of two IHBs with the same proton donor and two different proton acceptors (the proton acceptors are the $\mathrm{sp}^{2}$ hybridized oxygen atoms O 13 and O 10 ). These are known as bifurcated hydrogen bonds; the bifurcation is on the hydrogen atom H11. This bifurcation plays an important role in the stabilization of the conformers because it allows the presence of three simultaneous IHBs, while when there is no bifurcation, only two IHBs may be present. It may happen that, in some cases, the combined effects of these two IHBs can have comparable or greater stabilizing effect than the three IHBs of the $\mathrm{m} / \mathrm{p}$ conformers, but in the majority of cases, the three simultaneous IHBs have an overall greater stabilizing effect. The bifurcation affects the parameters of the IHBs ( $\mathrm{H} 11 \cdots \mathrm{O} 9 / \mathrm{H} 11 \cdots \mathrm{O} 13$ and $\mathrm{H} 11 \cdots \mathrm{O} 10 / \mathrm{H} 11 \cdots \mathrm{O} 13$ ) because the bond length in the case of bifurcation is longer than when the same IHB (H11 $\cdots \mathrm{O} 9$ or $\mathrm{H} 11 \cdots \mathrm{O} 13$ ) is present alone in a conformer. The presence of the bifurcated IHBs also causes a slight increase in the length of the $\mathrm{H} 14 \cdots \mathrm{O} 10$ and $\mathrm{H} 14 \cdots \mathrm{O} 9$ IHBs in comparison to the cases where one of these IHBs is present in a conformer when there are no bifurcated IHBs.

It is also interesting to note that $\mathrm{R}^{\prime}$ has some influence on the type of IHB formed. Comparisons of molecules with different $\mathrm{R}^{\prime}$ shows that $\mathrm{R}^{\prime}=$ pyrrolidine allows the possibility of conformers with only one IHB, namely H11 $\cdots$. 99 (while the N14-H14 bond does not form any IHB in those conformers). The nature of R has also some influence on the IHBs; for instance, it was found that $\mathrm{R}=$ cyclopropyl (group C) prevents the formation of non-bifurcated IHBs; this is typical of cyclopropyl and not of the other cyclic R considered. It has to be recalled also that the number of IHBs depends on the geometry of the thiourea group; therefore, this geometry has influence on the relative energies of the individual conformers across the compounds. The length of the chain between O7 and N18 also has some effect on conformational preferences. It was observed that the energy difference between the lowest energy conformer without any IHB and the highest energy conformer with at least one IHB is greatest in JP compounds ( J means $\mathrm{R}^{\prime}=$ morpholine and P means that there are three carbon atoms in the chain between O 7 and N 18 ).

The IR vibrational frequencies (harmonic approximations) are analyzed for the N11-H11 and N14-H14 bonds because they can form IHBs and the formation of the IHBs may affect the vibrational frequencies of the donor.

Red shifts (decrease of the vibrational frequency of the donor) are observed for $\mathrm{N} 14-\mathrm{H} 14$ when it forms $\mathrm{H} 14 \cdots \mathrm{O} 9$ or $\mathrm{H} 14 \cdots \mathrm{O} 10$, and the red shifts is greater for IHBs with shorter bond length (stronger IHBs). The most interesting thing - because it does not occur often - is the presence of blue shifts in the vibrational frequencies of the N11-H11 bond when it forms IHBs. In the DFT results, this blue shift is greater when N11-H11 forms a single IHB (H11 $\cdots$ O9 or H11 $\cdots 013$ ) than when it forms the bifurcated ones. The blue shifts are greater when the bond lengths of the IHBs formed by $\mathrm{N} 11-\mathrm{H} 11$ are longer (when the IHBs are weaker). This observation will require further investigation in future, through the consideration of additional sulfonylurea molecules. It is interesting to note that the situation discussed for these molecules is similar to the case where the amino $\mathrm{N}-\mathrm{H}$ bond forms an IHB with a possibility of bifurcation. This also suggests the importance of further investigation of the blue shifts in sulfonylureas.

The study considered also the energy corrected for ZPE and the Gibbs free energy. The trends of these energies, and of the uncorrected ones, are very similar for some of the compounds considered. Where there are some reversals in the relative energy sequences for some conformers, their differences are often marginal. The values of the ZPE corrected energy are often smaller than
those of the uncorrected energy. The values of the Gibbs free energies can be higher or lower than the values of the other quantities.

Besides the number and types of IHBs, other factors have some influence on the relative energies of the conformers. The influence by the nature of R and $\mathrm{R}^{\prime}$ mainly concerns the IHBs that can be formed, as already discussed. Conformers may also differ by the orientation of the R groups (except when $\mathrm{R}=$ methyl); however, these different orientations of R do not have much influence on the energy of the conformers (different orientation has been denoted with different lower-case letters combined with numbers in the naming of the conformers to facilitate comparisons). The relative energy of the individual conformers is also influenced by the orientation of the chain between O 7 and N18. It was found that the more stable orientations are parallel to the plane of the benzene ring (denoted by $\mathrm{q} / \mathrm{r}$ ) or perpendicular to the plane of the benzene ring (denoted by $\mathrm{s} / \mathrm{t}$ ). The influence of this orientation is however limited.

The dipole moments are influenced by the nature of $\mathrm{R}^{\prime}$ and also by the IHBs present. For all the conformers, the dipole moments are lower in the J compounds ( $\mathrm{R}^{\prime}=$ morpholine) than in the G ( $\mathrm{R}^{\prime}=$ pyrrolidine) and $\mathrm{L}\left(\mathrm{R}^{\prime}=\right.$ diethylamine) compounds. The IHBs do not have a significant influence on the dipole moments of the conformers with two or three IHBs ( k and $\mathrm{m} / \mathrm{p}$ conformers respectively). The $\mathrm{m} / \mathrm{p}$ and k conformers have very close dipole moments, while the dipole moment is lowest in the conformers with one IHB ( g conformers in G compounds) and highest in the conformers without any IHB (j conformers).

The HOMO-LUMO energy gaps show some dependence on the nature of $\mathrm{R}^{\prime}$. Considering the ranges of all the energy gaps of all the compounds considered, it can be established that $\mathrm{R}^{\prime}$ determines whether the range of the energy gaps is broad or narrow. The ranges of the HOMOLUMO energy gaps of the P and Q compounds (compounds with three or two carbon atoms in the chain between O 7 and N 18 , respectively) are not much different when $\mathrm{R}^{\prime}=$ pyrrolidine ( G compounds) and $\mathrm{R}^{\prime}=$ diethylamine ( L compounds), with some exceptions; the range width is slightly greater when $\mathrm{R}^{\prime}=$ morpholine ( J compounds). The distribution of the electron density for the HOMO and the LUMO depends on the conformer types and not significantly on the nature of R and R'. Similar distributions were observed in corresponding conformers across compounds, regardless of their $R$ and $R^{\prime}$. The electron density distribution is more on the benzene ring for most
conformers; the HOMO shows some distribution on O7 and N18, while for some conformers, the HOMO is distributed only on the $\mathrm{R}^{\prime}$ group.

The DFT and the HF results show a large number of similarities. There are some differences in the optimization results: in some cases, different inputs optimized to the same conformer with DFT and to different conformers with HF. This also means that the HF method gave more individual conformers than the DFT method for most of the compounds considered. The relative energies of the $\mathrm{q} / \mathrm{r}$ conformers are very similar with both DFT and HF, while the s/t conformers have higher relative energies in the HF results than in the DFT results. While the HOMO-LUMO energy-gap values are very different with DFT and HF, the width of the gap ranges for each compound do not differ much and are very close for the P and Q compounds.

DFT and HF differ also concerning the effects of the formation of the IHBs on the vibrational frequencies of the donor $(\mathrm{N}-\mathrm{H})$. When both $\mathrm{N} 11-\mathrm{H} 11$ and $\mathrm{N} 14-\mathrm{H} 14$ form IHBs, their simultaneous presence may influence the changes in their vibrational frequencies (the presence of each of the IHBs influences the vibrational frequency change of the donor of the other IHB). When N11-H11 forms bifurcated IHBs and N14-H14 also forms an IHB, the vibrational frequency of N11-H11 shows a blue shift with both DFT and HF, and the vibrational frequency of N14-H14 shows a red shift with DFT and may have either a red shift or a blue shift with HF, depending on the conformers. When N11-H11 forms H11 $\cdots$ O13 IHB and N14-H14 forms H14 $\cdots$ O10 IHB, the vibrational frequency of the N11-H11 bond shows a small blue shift with DFT and a small red shift with HF, and the vibrational frequency of N14-H14 show the greatest red shifts observed for these compounds with DFT and either a red shift or a blue shift with HF. When N11-H11 forms $\mathrm{H} 11 \cdots \mathrm{O} 9$ and $\mathrm{N} 14-\mathrm{H} 14$ does not form any IHB, the vibrational frequency of N11-H11 has comparatively great blue shifts with both DFT and HF.

### 5.2. Way forward

The study presented here is the first type of study that is performed on molecules, i.e., the conformational study in vacuo. The results are interesting, and so they suggest that it is very important to find additional information that is considered relevant to the study of biologically active molecules. Additional studies of these molecules in vacuo will involve the use of MP2,
because MP2 takes into account both correlation energy and dispersion contributions. It may also be interesting to try DFT calculations with another functional that can be considered suitable for these molecules and has different properties than B3LYP. Also details that have not been taken into account in the present study will be added, for example, the different geometries of the $\mathrm{R}^{\prime}$ moiety when it can take significantly different geometries, like in the case of $\mathrm{R}^{\prime}=$ morpholine, which may exhibit both the chair and the boat conformations.

Since these molecules are biologically active, it is important to study them in solution because the biological activity is exerted in solution; therefore, it is important to investigate how different solvents with different polarities affect the molecular properties. Solvents with different polarities will be considered because molecules in the organisms can be present in media with different polarities. The solvents will include water because water is the main component of the body.

The study will also expand to include other molecules, namely, molecules that are already in use in the treatment of diabetes, to enable comparisons of the molecular properties of the new sulfonylureas considered here and those that are being used. This will also be useful to search for pattern and similarities that will be suitable to understand the activities of these molecules, also in view of the fact that the activities of the compounds that are already in use are known. After enough information is collected, it will be possible to do Quantitative Structure-Activity Relationship (QSAR) analysis, trying to identify the new compounds that can be more active.

In addition, there will be studies investigating the interaction between all the molecules considered and proteins that are considered suitable targets in the treatment of diabetes.

## Chapter 6

## Tables and figures

This chapter presents the tables and figures showing the results for all the calculated conformers of each of the compounds considered. The compounds and their conformers are denoted with acronyms using the symbols shown in tables 4.2 and 4.4.

### 6.1. Tables

This section presents the tables reporting the values of the relevant quantities from the results obtained. The table for each set of related property are grouped in individual sections. For each property, individual tables are devoted to individual compounds. Each table reports the results from the $\mathrm{DFT} / \mathrm{B} 3 \mathrm{LYP} / 6-31+\mathrm{G}(\mathrm{d}, \mathrm{p})$ and $\mathrm{HF} / 6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ calculations in vacuo, respectively denoted as DFT and HF in the columns' headings (in the cases where different inputs optimized to the same geometry with the DFT results, the DFT energy values are repeated). All the calculations for conformational studies were done with totally relaxed geometry (full optimization). The conformers are listed in order of increasing DFT relative energies in all the tables.

### 6.1.1. Relative energies, HOMO-LUMO energy gaps and dipole moments of the conformers of each of the compounds considered.

This section presents the tables reporting the relative energies, HOMO-LUMO energy differences and dipole moments of the conformers of the compounds considered. Considering these quantities together helps investigate possible relationships between the relative energies and the other quantities. For instance, if two conformers have the same relative energies, dipole moments can be used to confirm whether the concerned conformers have the same or different geometry.

### 6.1.2. Uuncorrected relative energies, relative energies corrected for ZPE and Gibbs free energies and corresponding corrections for each compound considered.

In this section, tables 6.37-6.72 reports the uncorrected relative energy, relative energy corrected for ZPE (sum of electronic and zero-point energies) and Gibbs free energies (sum of electronic and thermal free energies) for the calculated conformers of all the compounds considered. Tables 6.73-6.108 reports the ZPE corrections to the electronic energy and thermal corrections to the Gibbs free energies for each of the compound considered. All these results were obtained through frequency calculations (harmonic-approximation).

Table 6.37. Uncorrected relative energy ( $\Delta \mathbf{E}, \mathrm{kcal} / \mathrm{mol}$ ), relative energy corrected for ZPE ( $\Delta \mathbf{E}_{\text {corrected }}$, $\mathrm{kcal} / \mathrm{mol}$ ) and Gibbs free energy ( $\Delta \mathrm{G}_{\text {corrected }} \mathrm{kcal} / \mathrm{mol}$ ) of the calculated conformers of compound AGP.
The absolute values for the lowest energy conformers for $\mathrm{E}_{\text {corrected }}$ are $-1604.386243 / \mathrm{DFT}$ (AGP-p-t-u3) and $-1596.173253 / \mathrm{HF}$ (AGP-m-r-u1); the absolute free energy of the lowest energy conformer is 1604.451283/DFT (AGP-p-t-u3) and -1596.236560/HF (AGP-m-r-u1).

6.1.3. Parameters of the intramolecular hydrogen bonds present in the calculated conformers of the compounds considered.

This section presents the tables reporting the parameters of the intramolecular hydrogen bonds (IHBs) present in the calculated conformers of the compounds considered. It can be recalled that the parameters of the IHBs are the following: bond length $(\mathrm{H} \cdots \mathrm{O})$, donor-acceptor distance $(\mathrm{N} \cdots \mathrm{O})$ and bond angle (NHO). For each conformer, the IHBs present are indicated individually. When two IHBs have the same donor (H11), it indicates that they are bifurcated on H11. Conformers with no IHBs do not appear in these tables ( j conformers).

Table 6.109. Parameters of the hydrogen bonds in the conformers of compound AGP.

| Conformers | IHB considered | $\mathrm{H} \cdots \mathrm{O}$ bond length <br> (A) |  | $\mathrm{N} \cdots \mathrm{O}$ distance $(\AA)$ |  | NHO bond angle ( ${ }^{\circ}$ ) |  |

6.1.4. The vibrational frequencies of the $\mathbf{N}-H$ bonds in the calculated conformers of each of the compounds considered.

This section presents the tables reporting the vibrational frequencies (harmonic approximations) of the $\mathrm{N}-\mathrm{H}$ bonds in the conformers of each of the compounds considered. The calculated frequencies were scaled by 0.9648 for DFT calculations and 0.8992 for HF calculations. When there are two values for the same bond and in the same conformer, it shows that they correspond to two vibrations that are coupled: the symmetric and asymmetric vibrations.

Table 6.145. Vibrational frequencies of $\mathrm{N} 11-\mathrm{H} 11$ and $\mathrm{N} 14-\mathrm{H} 14$ in the calculated conformers of compound AGP.
Symbols are used to indicate the symmetric (*) and asymmetric (э) vibrations

### 6.1.5. Changes in the vibrational frequencies, caused by the formation of IHBs.

This section presents the tables reporting the changes in the vibrational frequencies of $\mathrm{N} 11-\mathrm{H} 11$ and H14-H14 bonds when they form IHBs. The table also indicate the IHB formed by the given $\mathrm{N}-\mathrm{H}$ bonds. The changes are calculated as the difference between the average vibrational frequency of the given $\mathrm{N}-\mathrm{H}$ bond over the conformer where it does not form any IHB and its vibrational frequency in a conformer where it forms an IHB. In this way, a negative change indicates an increase of the vibrational frequency, that is a blue shift, and a positive change indicates a decrease of the vibrational frequencies, that is a red shift.

Table 6.181. Changes in the IR vibrational frequencies of the N11-H11 and $\mathrm{N} 14-\mathrm{H} 14$ bonds in the conformers of compound AGP containing IHBs.

| Conformers | Vibrational frequency change ( $\mathrm{cm}^{-1}$ ) |  |  |  |  |  |

### 6.2. Figures presenting molecular structures

This section presents the figures of the molecular structures of the optimized geometries of all the calculated conformers and the shapes of the HOMO and LUMO frontier molecular orbitals. The results are obtained from full optimization calculations. The conformers are listed in order of increasing DFT relative energy. All the figures are presented with a similar orientation (the thiourea group on the right side of the benzene ring, and the chain to which $\mathrm{R}^{\prime}$ is attached on the left side of the benzene ring) to facilitate geometry comparisons.

### 6.2.1. Optimized geometries of the calculated conformers of all the compounds considered.

This section presents the figures of the optimized geometries of the calculated conformers of each of the compounds considered. The geometries reported are from the HF results. This is because some of the inputs optimized to the same conformer with DFT calculations, and it is interesting to view the additional conformers obtained from HF calculations (Appendix A show the inputs which optimized to the same output). In most cases conformers, the geometry types are similar in the DFT and HF results, and the interesting parameters to differentiate are the parameters of the IHBs which are reported in tables separately (section 6.1.3).

6.2.2. Shapes of the frontier molecular orbitals (HOMO and LUMO) of the calculated conformers of the compounds considered.

This section presents the shapes of the HOMO and LUMO for the calculated conformers of each of the compounds considered. The shapes are from the HF results (for the same reasons explained in section 6.2.1). HOMO and LUMO is indicated next to the names of each of the conformers in all the tables.

### 6.3. Figures presenting comparative diagrams for the energy values.

This section presents comparative diagrams of the relative energies of the conformers for each of the compounds considered. The conformers are denoted by numbers along the x -axis, for space reasons; each diagram has an associated table indicating the number (\#) representing the individual conformers. All the conformers are listed in order of DFT relative energy. In some of the diagrams, straight line-segments are used instead of curves for clarity reasons and to prevent the curves from extending to the negative section.
6.3.1. Diagrams comparing the HF and DFT relative energies of the calculated conformers of each of the compounds considered.

This section presents the diagrams comparing the HF and DFT relative energies of the calculated conformers of each of the compounds considered. The HF and DFT series are represented by different colors: blue for DFT and orange for HF.

Figure 6.73. Diagrams comparing the DFT ( -- ) and HF ( $-\infty$ ) relative energies of the calculated conformers of compound AGP.

| conformers | $\#$ | Conformers | $\#$ | Conformers | $\#$ | Conformers | $\#$ |

### 6.3.2. Diagrams comparing the uncorrected relative energy ( $\Delta \mathbf{E}$ ), relative energy corrected for ZPE ( $\Delta \mathbf{E}_{\text {corrected }}$ ) and Gibbs free energy ( $\Delta \mathbf{G}$ ) of the conformers of each of the compounds considered.

This section presents diagrams comparing the uncorrected relative energies ( $\Delta \mathrm{E}$ ), relative energies corrected for ZPE (sum of electronic and zero-point energies, $\Delta \mathrm{E}_{\text {corrected }}$ ) and Gibbs free energies (sum of electronic and thermal free energies, $\Delta \mathrm{G}$ ). The energy series are represented by different colours: blue for $\Delta \mathrm{E}$, orange for $\Delta \mathrm{E}_{\text {corrected }}$ and green for $\Delta \mathrm{G}$.

For each compound, separated diagrams are made for the DFT and HF results (respectively denoted as DFT and HF and indicated on top of each diagrams). In both HF and DFT diagrams, the conformers are listed in order of increasing DFT relative energies; for this reason, there might be cases in which the HF results show apparently abnormal behaviour (not always increasing; for example, figures 6.112 and 6.115), when there are discrepancies in the relative energy sequence between the DFT and HF results.

## Appendix A

This section presents additional tables which may be useful in the analysis of results. In the tables for inputs and output geometries, ml and m 2 indicates different geometries considered in the preparation of inputs.

Table A1. Input geometries and resulting optimized conformers for compound AGP.

| Inputs | Outputs |
| :--- | :--- |
| AGP-m1-r | AGP-m-r-u1 |
| AGP-m1-t |  |
| AGP-m1-s | AGP-m-s-u1 |
| AGP-p-s | AGP-p-t-u3 |
| AGP-m1-q | AGP-m-q-u1 |
| AGP-p-q | AGP-p-r-u3 |
| AGP-k-r | AGP-k-q-u1 |
| AGP-k-q | AGP-k-r-u1 |
| AGP-k-s | AGP-m-r-u2 |
| AGP-m2-q |  |
| AGP-m2-t |  |
| AGP-m2-s |  |
| AGP-g-q | AGP-g-q-u3 |
| AGP-g-t | AGP-j-q-u3 |
| AGP-g-s | AGP-j-r-u3 |
| AGP-g-r |  |
| AGP-j-r | AGP-j-s-u3 |
| AGP-j-q |  |
| AGP-j-s |  |
| AGP-j-t |  |

Table A2. Input geometries and resulting optimized conformers for compound AGQ.

| Inputs | Outputs |
| :--- | :--- |
| AGQ-m1-s | AGQ-m-r-u1 |
| AGQ-m1-r |  |
| AGQ-p-s |  |
| AGQ-p-r | AGQ-m-q-u1 |
| AGQ-m1-q |  |
| AGQ-p-q |  |
| AGQ-p-t | AGQ-k-q-u1 |
| AGQ-m1-t |  |
| AGQ-k-s |  |

| AGQ-k-r |  |
| :--- | :--- |
| AGQ-k-q | AGQ-k-r-u1 |
| AGQ-k-t | AGQ-m-r-u2 |
| AGQ-m2-q |  |
| AGQ-m2-t |  |
| AGQ-m2-s | AGQ-g-r-u3 |
| AGQ-m2-r | AGQ-g-t-u3 |
| AGQ-g-q | AGQ-g-q-u3 |
| AGQ-g-t | AGQ-j-q-u3 |
| AGQ-g-s | AGQ-j-r-u3 |
| AGQ-g-r |  |
| AGQ-j-r | AGQ-j-t-u3 |
| AGQ-j-q |  |
| AGQ-j-t |  |

Table A3. Input geometries and resulting optimized conformers for compound AJP.

| Inputs | Outputs |
| :---: | :---: |
| AJP-m1-s | AJP-m-r-u1 |
| AJP-m1-r |  |
| AJP-p-s |  |
| AJQ-p-r |  |
| AJP-m1-t | AJP-m-s-u1 |
| AJP-p-t |  |
| AJP-m1-q | AJP-m-q-u1 |
| AJP-p-q |  |
| AJP-g-r | AJP-k-q-u1 |
| AJP-k-r |  |
| AJP-g-q | AJP-k-r-u1 |
| AJP-g-s |  |
| AJP-k-q |  |
| AJP-k-s |  |
| AJP-g-t | AJP-k-s-u1 |
| AJP-k-t |  |
| AJP-m2-q | AJP-m-r-u2 |
| AJP-m2-s |  |
| AJP-m2-t | AJP-m-s-u2 |
